## Python 2.4 Quick Reference

## Contents

- Front matter
- Invocation Options
- Environment variables
- Lexical entities : keywords, identifiers, string literals, boolean constants, numbers, sequences, dictionaries, operators
- Basic types and their operations: None, bool, Numeric types, sequence types, list, dictionary, string, file, sets
- Advanced types
- Statements: assignment, control flow, exceptions, name space, function def, class def
- Iterators; Generators; Descriptors; Decorators
- Built-in Functions
- Built-in Exceptions
- Standard methods \& operators redefinition in user-created Classes
- Special informative state attributes for some types
- Important modules : sys, os, posix, posixpath, shutil, time, string, re, math, getopt
- List of modules in the base distribution
- Workspace exploration and idiom hints
- Python mode for Emacs

## Front matter

Version 2.4
The latest version is to be found here.
Please report errors, inaccuracies and suggestions to Richard Gruet (pqr at rgruet.net).
Last modified on Feb 20, 2005
17 Feb 2005,
upgraded by Richard Gruet for Python 2.4

Tip: From within the Python interpreter, type help, help (object) or help ("name") to get help.

## Invocation Options

python[w] [-dEhimOQStuUvVWxX?] [-c command | scriptFile |-] [args]
(pythonw does not open a terminal/console; python does)

| Invocation Options |  |
| :--- | :--- |
| Option | Effect |
| - d | Output parser debugging information (also PYTHONDEBUG $=x$ ) |
| - E | Ignore environment variables (such as PYTHONPATH) |
| $-h$ | Print a help message and exit (formerly - ?) |, | Inspect interactively after running script (also PYTHONINSPECT=x) and force prompts, even if stdin appears not to be |
| :--- |
| a terminal. |
| - |

- Available IDEs in std distrib: IDLE (tkinter based, portable), Pythonwin (on Windows). Other free IDEs: IPython (enhanced interactive Python shell), SPE, BOA constructor.
- Typical python module header :

```
#!/usr/bin/env python
# -*- coding: latin1 -*-
```

Since 2.3 the encoding of a Python source file must be declared as one of the two first lines (or defaults to 7 bits Ascii) [PEP-0263], with the format:

```
# -*- coding: encoding -*-
```

Std encodings are defined here, e.g. ISO-8859-1 (aka latin1), iso-8859-15 (latin9), UTF-8... Not all encodings supported, in particular UTF-16 is not supported.

## Environment variables

| Environment variables | Effect |
| :--- | :--- |
| Variable | Alternate prefix directory (or prefix;exec_prefix). The default module search path uses prefix/lib |
| PYTHONHOME | Augments the default search path for module files. The format is the same as the shell's $\$$ SATH: one or <br> more directory pathnames separated by ':' or ';' without spaces around (semi-) colons ! <br> On Windows first search for Registry key <br> HKEY_LoCAL_MACHINE $\backslash$ Software $\backslash$ Python\Pythoncore $\backslash x . y \backslash$ PythonPath (default value). You may also define <br> a key named after your application with a default string value giving the root directory path of your app. <br> Alternatively, you can create a text file in the Python home directory with a .pth extension, containing the <br> path (one per line). |
| PYTHONPATH |  |
| PYTHONSTARTUP | If this is the name of a readable file, the Python commands in that file are executed before the first prompt <br> is displayed in interactive mode (no default). |
| PYTHONDEBUG | If non-empty, same as -d option |$|$| PYTHONINSPECT | If non-empty, same as -i option |
| :--- | :--- |
| PYTHONOPTIMIZE | If non-empty, same as -O option |
| PYTHONUNBUFFERED | If non-empty, same as -u option |
| PYTHONVERBOSE | If non-empty, same as -v option |
| PYTHONCASEOK | If non-empty, ignore case in file/module names (imports) |

## Notable lexical entities

## Keywords

| assert | elif | from | lambda | return |
| :--- | :--- | :--- | :--- | :--- |
| break | else | global | not | try |
| class | except | if | or | while |
| continue | exec | import | pass | yield |
| def | finally | in | print |  |

- (List of keywords available in std module: keyword)
- Illegitimate Tokens (only valid in strings): \$ ? (plus @ before 2.4)
- A statement must all be on a single line. To break a statement over multiple lines, use "\", as with the C preprocessor.
Exception: can always break when inside any (), [], or \{\} pair, or in triple-quoted strings.
- More than one statement can appear on a line if they are separated with semicolons (";").
- Comments start with "\#" and continue to end of line.

## Identifiers

```
(letter | "_") (letter | digit | "_")*
```

- Python identifiers keywords, attributes, etc. are case-sensitive.
- Special forms: _ident (not imported by 'from module import *'); __ident__ (system defined name); __ident (classprivate name mangling).

## String literals

| Literal |
| :--- |
| "a string enclosed by double quotes" |
| 'another string delimited by single quotes and with a " inside' |
| "'a string containing embedded newlines and quote (') marks, can be delimited with triple quotes.'"' |
| "'" may also use 3- double quotes as delimiters """ |
| u'a unicode string' |
| U"Another unicode string" |
| r'a raw string where \are kept (literalized): handy for regular expressions and windows paths!' |
| R"another raw string" -- raw strings cannot end with a \} $\\ {\hline \text { ur'a unicode raw string' }} \\ {\hline \text { UR"another raw unicode" }} \\ {\hline}$ |

- Use \at end of line to continue a string on next line.
- Adjacent strings are concatened, e.g. 'Monty ' 'Python' is the same as 'Monty Python'.
- u'hello' + ' world' --> u'hello world' (coerced to unicode)

| String Literal Esca |  |
| :---: | :---: |
| Escape | Meaning |
| \newline | Ignored (escape newline) |
| \1 | Backslash ( |
| ) |  |
| \e | Escape (ESC) |
| \v | Vertical Tab (VT) |
| \' | Single quote (') |
| \f | Formfeed (FF) |
| \000 | char with octal value 000 |
| \" | Double quote (") |
| \n | Linefeed (LF) |
| \a | Bell (BEL) |
| \r | Carriage Return (CR) |
| \xhh | char with hex value $h h$ |
| \b | Backspace (BS) |
| \t | Horizontal Tab (TAB) |
|  | Character with 16-bit hex value $x x x x$ (unicode only) |
| \UXXXXXXXXX | Character with 32-bit hex value $x x x x x x x x$ (unicode only) |
| \N\{name\} | Character named in the Unicode database (unicode only), e.g. u' $\backslash \mathrm{N}\{\mathrm{Greek}$ Small Letter Pi\}' <=> u'\u03c0'. <br> (Conversely, in module unicodedata, |
| \AnyOtherChar | left as-is, including the backslash, e.g. str ('\z') == ' |
| z' |  |

- NUL byte ( $\backslash 000$ ) is not an end-of-string marker; NULs may be embedded in strings.
- Strings (and tuples) are immutable: they cannot be modified.

## Boolean constants

- True
- False

In 2.2, True and False are integers 1 and 0 . Since 2.3, they are of new type bool.

## Numbers

- Decimal integer: 1234, 1234567890546378940L (or I)
- Octal integer: 0177, 0177777777777777777L (begin with a 0)
- Hex integer: 0xFF, 0XFFFFffffFFFFFFFFFFL (begin with 0x or 0X)
- Long integer (unlimited precision): 1234567890123456L (ends with L or I) or long(1234)
- Float (double precision): 3.14e-10, .001, 10., 1E3
- Complex: 1J, $2+3 \mathbf{J}, 4+5 \mathbf{j}$ (ends with $\mathbf{J}$ or $\mathbf{j}$, + separates (float) real and imaginary parts)

Integers and long integers are unified starting from release 2.2 (the $\mathbf{L}$ suffix is no longer required)

## Sequences

- Strings (type str) of length $0,1,2$ (see above)
', '1', "12", 'hello\n'
- Tuples (type tuple) of length $0,1,2$, etc:
() $(1),(1,2)$ \# parentheses are optional if len $>0$
- Lists (type list) of length $0,1,2$, etc:
[] [1] [1,2]
- Indexing is $\mathbf{0}$-based. Negative indices (usually) mean count backwards from end of sequence.
- Sequence slicing [starting-at-index : but-less-than-index [: step]]. Start defaults to 0, end to len(sequence), step to 1.

```
a = (0,1,2,3,4,5,6,7)
    a[3] == 3
    a[-1] == 7
    a[2:4] == (2, 3)
    a[1:] == (1, 2, 3, 4, 5, 6, 7)
    a[:3] == (0, 1, 2)
    a[:] == (0,1,2,3,4,5,6,7) # makes a copy of the sequence.
    a[::2] == (0, 2, 4, 6) # Only even numbers.
    a[::-1] = (7, 6, 5, 4, 3 , 2, 1, 0) # Reverse order.
```

## Dictionaries (Mappings)

```
Dictionaries (type dict) of length 0, 1, 2, etc: {} {1 : 'first'} {1 : 'first', 'next': 'second'}
```

## Operators and their evaluation order

| Operators and their evaluation order |  |  |
| :---: | :---: | :---: |
| Highest | Operator | Comment |
|  | , [...] \{...\} `... | Tuple, list \& dict. creation; string conv. |
|  | S[i] s[i:j] s.attr f(...) | indexing \& slicing; attributes, fct calls |
|  | +x, -x, ~x | Unary operators |
|  | $x^{* *} y$ | Power |
|  | $\mathrm{x}^{*} \mathrm{y} x / \mathrm{y}$ x\% ${ }^{\text {c }}$ | mult, division, modulo |
|  | $x+y$ x-y | addition, substraction |
|  | $x \ll y \quad x \gg y$ | Bit shifting |
|  | $x \boldsymbol{*} y$ | Bitwise and |
|  | $x^{\wedge} \mathrm{y}$ | Bitwise exclusive or |
|  | $x$ x ${ }^{\text {d }}$ | Bitwise or |
|  | $\begin{aligned} & x<y x<=y x>y x>=y \quad x==y x!=y x<>y \\ & x \text { is } y x \text { is not } y \\ & x \text { in } s x \text { not in } s \end{aligned}$ | Comparison, identity, membership |
|  | not $x$ | boolean negation |
|  | $x$ and $y$ | boolean and |
|  | $x$ or y | boolean or |
| Lowest | lambda args: expr | anonymous function |

- Alternate names are defined in module operator (e.g. __add __ and add for +)
- Most operators are overridable

## Basic types and their operations

## Comparisons (defined between any types)

| Comparisons |  | Notes |
| :--- | :--- | :---: |
| Comparison | Meaning | $(1)$ |
| $\mathbf{<}$ | strictly less than |  |
| $\boldsymbol{<}$ | less than or equal to |  |
| $\boldsymbol{>}$ | strictly greater than |  |
| $\boldsymbol{>}=$ | greater than or equal to |  |
| $\mathbf{=}$ | equal to |  |
| $\mathbf{I}$ or <> | not equal to |  |
| is | object identity | $(2)$ |
| is not | negated object identity | $(2)$ |

Notes:

- Comparison behavior can be overridden for a given class by defining special method $\qquad$ cmp__ .
- (1) $X<Y<Z<W$ has expected meaning, unlike C
- (2) Compare object identities (i.e. id(object)), not object values.

## None

- None is used as default return value on functions. Built-in single object with type NoneType. Might become a keyword in the future.
- Input that evaluates to None does not print when running Python interactively.
- None is now a constant; trying to bind a value to the name "None" is now a syntax error.

## Boolean operators

| Boolean values and operators | Evaluates to | Notes |
| :--- | :--- | :--- |
| Value or Operator | True if expr is true, False otherwise. | see True, False |
| built-in bool(expr) | considered False |  |
| None, numeric zeros, empty sequences and mappings | considered True |  |
| all other values | True if $x$ is False, else False |  |
| not $x$ | if $x$ is False then $y$, else $x$ | $(1)$ |
| $x$ or $y$ | if $x$ is False then $x$, else $y$ | $(1)$ |
| $x$ and $y$ |  |  |

Notes:

- Truth testing behavior can be overridden for a given class by defining special method $\qquad$ .
- (1) Evaluate second arg only if necessary to determine outcome.

## Numeric types

Floats, integers, long integers, Decimals.

- Floats (type float) are implemented with C doubles.
- Integers (type int) are implemented with C longs (signed 32 bits, maximum value is sys.maxint)
- Long integers (type long) have unlimited size (only limit is system resources).
- Integers and long integers are unified starting from release 2.2 (the $\mathbf{L}$ suffix is no longer required). int () returns a long integer instead of raising OverflowError. Overflowing operations such as $2 \ll 32$ no longer trigger FutureWarning and return a long integer.
- Since 2.4, new type Decimal introduced (see module: decimal) to compensate for some limitations of the floating point type, in particular with fractions. Unlike floats, decimal numbers can be represented exactly; exactness is preserved in calculations; precision is user settable via the context type [PEP 327].

Operators on all numeric types

| Operators on all numeric types |  |
| :--- | :--- |
| Operation | Result |
| abs $(x)$ | the absolute value of $x$ |
| int $(x)$ | $x$ converted to integer |
| long $(x)$ | $x$ converted to long integer |
| float $(x)$ | $x$ converted to floating point |
| $-x$ | $x$ negated |
| $+x$ | $x$ unchanged |
| $x+y$ | the sum of $x$ and $y$ |
| $x-y$ | difference of $x$ and $y$ |
| $x * y$ | product of $x$ and $y$ |
| $x / y$ | true division of $x$ by $y: 1 / 2->0.5(1)$ |
| $x / / y$ | floor division operator: $1 / / 2->0(1)$ |
| $x \% y$ | remainder of $x / y$ |
| divmod $(x, y)$ | the tuple $(x / y, x \% y)$ |
| $x^{* *} y$ | $x$ to the power $y$ (the same as pow $(x, y))$ |

## Notes

- (1) / is still a floor division $(1 / 2=0)$ unless validated by a from __future__ import division.
- classes may override methods $\qquad$ truediv and $\qquad$ floordiv to redefine these operators.

Bit operators on integers and long integers

| Bit operators |  |
| :--- | :--- |
| Operation | Result |
| $\sim x$ | the bits of $x$ inverted |
| $x^{\wedge} y$ | bitwise exclusive or of $x$ and $y$ |
| $x \& y$ | bitwise and of $x$ and $y$ |
| $x \mid y$ | bitwise or of $x$ and $y$ |
| $x \ll n$ | $x$ shifted left by $n$ bits |
| $x \gg n$ | $x$ shifted right by $n$ bits |

Complex Numbers

- Type complex, represented as a pair of machine-level double precision floating point numbers.
- The real and imaginary value of a complex number z can be retrieved through the attributes z.real and z.imag.

Numeric exceptions
TypeError
raised on application of arithmetic operation to non-number
OverflowError

## Operations on all sequence types (lists, tuples, strings)

| Operations on all sequence types |  |  |
| :---: | :---: | :---: |
| Operation | Result | Notes |
| $x$ in s | True if an item of $s$ is equal to $x$, else False | (3) |
| $x$ not in $s$ | False if an item of $s$ is equal to $x$, else True | (3) |
| $s+t$ | the concatenation of $s$ and $t$ |  |
| $s$ * $n, n * s$ | $n$ copies of $s$ concatenated |  |
| s[i] | $i '$ th item of $s$, origin 0 | (1) |
| $\begin{aligned} & s[i: j] \\ & s[i: j: \text { step }] \end{aligned}$ | Slice of $s$ from $i$ (included) to $j$ (excluded). Optional step value, possibly negative (default: 1 ). | (1), (2) |
| len(s) | Length of $s$ |  |
| $\min (s)$ | Smallest item of $s$ |  |
| $\max (\mathrm{s})$ | Largest item of (s) |  |
| reversed(s) | [2.4] Returns an iterator on $s$ in reverse order. $s$ must be a sequence, not an iterator (use reversed(list(s)) in this case. [PEP 322] |  |
| sorted (iterable [, cmp] <br> [, cmp $=\mathrm{cmpFct}$ ] <br> [, key=keyGetter] <br> [, reverse=bool]) | [2.4] works like the new in-place list.sort(), but sorts a new list created from the iterable. |  |

## Notes:

- (1) if $i$ or $j$ is negative, the index is relative to the end of the string, ie len(s) $+i$ or len(s) $+j$ is substituted. But note that -0 is still 0 .
- (2) The slice of $s$ from $i$ to $j$ is defined as the sequence of items with index $k$ such that $i<=k<j$. If $i$ or $j$ is greater than len(s), use len(s). If $i$ is omitted, use len(s). If $i$ is greater than or equal to $j$, the slice is empty.
- (3) For strings: before $2.3, \mathrm{x}$ must be a single character string; Since 2.3 , x in s is True if x is a substring of s .

## Operations on mutable sequences (type list)

| Operations on mutable sequences |  |  |
| :---: | :---: | :---: |
| Operation | Result | Notes |
| $s[i]=x$ | item $i$ of $s$ is replaced by $x$ |  |
| $s[i: j$ [:step] $]=t$ | slice of $s$ from $i$ to $j$ is replaced by $t$ |  |
| del $s[i: j[: s t e p]]$ | same as $s[i: j]=[]$ |  |
| s.append ( $x$ ) | same as $s[\operatorname{len}(s): \operatorname{len}(s)]=[x]$ |  |
| s.extend ( $x$ ) | same as $s[\operatorname{len}(s): \operatorname{len}(s)]=x$ | (5) |
| s.count ( $x$ ) | returns number of $i$ 's for which $s[i]==x$ |  |
| s.index( $x$ [, start[, stop]]) | returns smallest $i$ such that $s[i]==x$. start and stop limit search to only part of the list. | (1) |
| s.insert( $i, x$ ) | same as s[i:i] $=[x]$ if $i>=0 . i==-1$ inserts before the last element. |  |
| s.remove( $x$ ) | same as del s[s.index $(x)$ ] | (1) |
| s.pop([i]) | same as $\mathrm{x}=\mathrm{s}[\mathrm{i}]$; del $\mathrm{s}[\mathrm{i}]$; return x | (4) |
| s.reverse() | reverses the items of $s$ in place | (3) |
| ```s.sort([cmp ]) s.sort([cmp=cmpFct] [, key=keyGetter] [, reverse=bool])``` | sorts the items of $s$ in place | (2), (3) |

Notes:

- (1) Raises a ValueError exception when $x$ is not found in $s$ (i.e. out of range).
- (2) The sort() method takes an optional argument cmp specifying a comparison function takings 2 list items and returning $-1,0$, or 1 depending on whether the 1 st argument is considered smaller than, equal to, or larger than the 2nd argument. Note that this slows the sorting process down considerably. Since 2.4 , the cmp argument may be specified as a keyword, and 2 optional keywords args are added: key is a fct that takes a list item and returns the key to use in the comparison (faster than cmp); reverse: If True, reverse the sense of the comparison used. Since Python 2.3 (?), the sort is guaranteed "stable". This means that two entries with equal keys will be returned in the same order as they were input. For example, you can sort a list of people by name, and then sort the list by age, resulting in a list sorted by age where people with the same age are in name-sorted order.
- (3) The sort () and reverse () methods modify the list in place for economy of space when sorting or reversing a large list. They don't return the sorted or reversed list to remind you of this side effect.
- (4) The pop () method is not supported by mutable sequence types other than lists. The optional argument i defaults to -1 , so that by default the last item is removed and returned.
- (5) Raises a TypeError when x is not a list object.

Operations on mappings / dictionaries (type dict)

| Operations on mappings | Result |  |
| :--- | :--- | :--- |
| Operation | The number of items in $d$ | Notes |
| $\boldsymbol{l e n ( d )}$ | Creates an empty dictionary. <br> Creates a dictionary init with the keyword args kwargs. <br> Creates a dictionary init with (key, value) pairs provided by iterable. |  |
| $\boldsymbol{\operatorname { d i c t } ( )}$dict $(* *$ kwargs) <br> $\operatorname{dict(\text {(iterable)}}$ |  |  |

| $\operatorname{dict}(\mathrm{d})$ | Creates a dictionary which is a copy of dictionary $d$. |  |
| :---: | :---: | :---: |
| d.fromkeys(iterable, value=None) | Class method to create a dictionary with keys provided by iterator, and all values set to value. |  |
| $d[k]$ | The item of $d$ with key $k$ | (1) |
| $d[k]=\mathrm{x}$ | Set $d[k]$ to $x$ |  |
| del $d[k]$ | Removes $d[k]$ from $d$ | (1) |
| d.clear() | Removes all items from $d$ |  |
| d.copy() | A shallow copy of $d$ |  |
| $\begin{aligned} & \text { d.has_key }(k) \\ & k \text { in } d \end{aligned}$ | True if $d$ has key $k$, else False |  |
| d.items() | A copy of d's list of (key, item) pairs | (2) |
| d.keys() | A copy of d's list of keys | (2) |
| d1.update(d2) | for $k, v$ in $d 2$.items(): $d 1[k]=v$ <br> Since 2.4, update(**kwargs) and update(iterable) may also be used. |  |
| d.values() | A copy of $d$ 's list of values | (2) |
| d.get( $k$, defaultval) | The item of $d$ with key $k$ | (3) |
| d.setdefault(k[,defaultval]) | $d[k]$ if $k$ in $d$, else defaultval(also setting it) | (4) |
| d.iteritems() | Returns an iterator over (key, value) pairs. |  |
| d.iterkeys() | Returns an iterator over the mapping's keys. |  |
| d.itervalues() | Returns an iterator over the mapping's values. |  |
| d.pop(k[, default]) | Removes key $k$ and returns the corresponding value. If key is not found, default is returned if given, otherwise KeyError is raised. |  |
| d.popitem() | Removes and returns an arbitrary (key, value) pair from d |  |

Notes:

- TypeError is raised if key is not acceptable.
- (1) KeyError is raised if key $k$ is not in the map.
- (2) Keys and values are listed in random order.
- (3) Never raises an exception if $k$ is not in the map, instead it returns defaultval. defaultval is optional, when not provided and $k$ is not in the map, None is returned.
- (4) Never raises an exception if $k$ is not in the map, instead returns defaultVal, and adds $k$ to map with value defaultVal. defaultVal is optional. When not provided and $k$ is not in the map, None is returned and added to map.

## Operations on strings (type str)

These string methods largely (but not completely) supersede the functions available in the string module.
The str and unicode types share a common base class basestring.

| Operations on strings |  |  |
| :---: | :---: | :---: |
| Operation | Result | Notes |
| s.capitalize() | Returns a copy of $s$ with only its first character capitalized. |  |
| s.center(width) | Returns a copy of $s$ centered in a string of length width. | (1) |
| s.count(sub[ , start[,end]]) | Returns the number of occurrences of substring sub in string s. | (2) |
| s.encode([ encoding[,errors]]) | Returns an encoded version of $s$. Default encoding is the current default string encoding. | (3) |
| ```s.endswith(suffix [,start [,end]])``` | Returns True if $s$ ends with the specified suffix, otherwise return false. | (2) |
| s.expandtabs([ tabsize]) | Returns a copy of $s$ where all tab characters are expanded using spaces. | (4) |
| s.find(sub[ ,start[,end]]) | Returns the lowest index in $s$ where substring sub is found. Returns -1 if sub is not found. | (2) |
| s.index(sub[ start[,end]]) | like find(), but raises ValueError when the substring is not found. | (2) |
| s.isalnum() | Returns True if all characters in $s$ are alphanumeric, False otherwise. | (5) |
| s.isalpha() | Returns True if all characters in $s$ are alphabetic, False otherwise. | (5) |
| s.isdigit() | Returns True if all characters in $s$ are digit characters, False otherwise. | (5) |
| s.islower() | Returns True if all characters in $s$ are lowercase, False otherwise. | (6) |
| s.isspace() | Returns True if all characters in $s$ are whitespace characters, False otherwise. | (5) |
| s.istitle() | Returns True if string $s$ is a titlecased string, False otherwise. | (7) |
| s.isupper() | Returns True if all characters in s are uppercase, False otherwise. | (6) |
| separator.join(seq) | Returns a concatenation of the strings in the sequence seq, separated by string separator, e.g.: |  |
| $\begin{aligned} & \text { s.ljust/rjust/center(width[, } \\ & \text { fillChar=' }] \text { ) } \end{aligned}$ | Returns s left/right justified/centered in a string of length width. | (1), (8) |
| s.lower() | Returns a copy of $s$ converted to lowercase. |  |
| s.Istrip([chars] ) | Returns a copy of $s$ with leading chars (default: whitespaces) removed. |  |
| s.replace(old, new[, maxCount $=-1$ ]) | Returns a copy of $s$ with the first maxCount ( -1 : unlimited) occurrences of substring old replaced by new. | (9) |
| s.rfind(sub[, start[, end]]) | Returns the highest index in $s$ where substring sub is found. Returns -1 if sub is not found. | (2) |
| s.rindex(sub [, start[, end]]) | like rfind(), but raises valueError when the substring is not found. | (2) |
| s.rjust(width) | Returns s right justified in a string of length width. | (1), (8) |
| s.rstrip([chars]) | Returns a copy of $s$ with trailing chars(default: whitespaces) removed. |  |
| s.split([ separator[, maxsplit]]) | Returns a list of the words in s, using separator as the delimiter string. | (10) |
| s.rsplit([ separator[, maxsplit]]) | Same as split, but splits from the end of the string. | (10) |
| s.splitlines([ keepends]) | Returns a list of the lines in $s$, breaking at line boundaries. | (11) |
| ```s.startswith(prefix [, start[, end]])``` | Returns True if $s$ starts with the specified prefix, otherwise returns False. Negative numbers may be used for start and end | (2) |

| s.strip([chars]) | Returns a copy of $s$ with leading and trailing chars(default: whitespaces) removed. |  |
| :--- | :--- | :--- |
| s.swapcase() | Returns a copy of $s$ with uppercase characters converted to lowercase and vice <br> versa. |  |
| s.title() | Returns a titlecased copy of $s$, i.e. words start with uppercase characters, all <br> remaining cased characters are lowercase. |  |
| s.translate(table [, <br> deletechars]) | Returns a copy of $s$ mapped through translation table table. | (12) |
| s.upper() | Returns a copy of $s$ converted to uppercase. |  |
| s.zfill(width) | Returns the numeric string left filled with zeros in a string of length width. |  |

Notes:

- (1) Padding is done using spaces or the given character.
- (2) If optional argument start is supplied, substring $s$ [start:] is processed. If optional arguments start and end are supplied, substring $s$ [start:end] is processed.
- (3) Optional argument errors may be given to set a different error handling scheme. The default for errors is 'strict', meaning that encoding errors raise a ValueError. Other possible values are 'ignore' and 'replace'.
- (4) If optional argument tabsize is not given, a tab size of 8 characters is assumed.
- (5) Returns False if string $s$ does not contain at least one character.
- (6) Returns False if string $s$ does not contain at least one cased character.
- (7) A titlecased string is a string in which uppercase characters may only follow uncased characters and lowercase characters only cased ones
- (8) $s$ is returned if width is less than len(s).
- (9) If the optional argument maxsplit is given, only the first maxsplit occurrences are replaced.
- (10) If sep is not specified or None, any whitespace string is a separator. If maxsplit is given, at most maxsplit splits are done.
- (11) Line breaks are not included in the resulting list unless keepends is given and true.
- (12) table must be a string of length 256. All characters occurring in the optional argument deletechars are removed prior to translation.

String formatting with the \% operator
formatString \% args --> evaluates to a string

- formatString uses C printf format codes : \%, c, s, i, d, u, o, x, X, e, E, f, g, G, r (details below).
- Width and precision may be $a *$ to specify that an integer argument gives the actual width or precision.
- The flag characters -, +, blank, \# and 0 are understood (details below).
- \%s will convert any type argument to string (uses str() function)
- args may be a single arg or a tuple of args
- Right-hand-side can also be a mapping:
$\mathrm{a}=\mathrm{\prime} \%(\mathrm{l}$ ang) s has \% (c) 03d quote types.' \% \{'c':2, 'lang':'Python'\}
(vars () function very handy to use on right-hand-side)

| Format codes |  |
| :---: | :--- |
| Code | Meaning |
| d | Signed integer decimal. |
| i | Signed integer decimal. |
| o | Unsigned octal. |
| u | Unsigned decimal. |
| x | Unsigned hexadecimal (lowercase). |
| X | Unsigned hexadecimal (uppercase). |
| e | Floating point exponential format (lowercase). |
| E | Floating point exponential format (uppercase). |
| f | Floating point decimal format. |
| F | Floating point decimal format. |
| g | Same as "e" if exponent is greater than -4 or less than precision, "f" otherwise. |
| G | Same as "E" if exponent is greater than -4 or less than precision, "F" otherwise. |
| c | Single character (accepts integer or single character string). |
| r | String (converts any python object using repr ()). |
| s | String (converts any python object using str ()). |
| $\%$ | No argument is converted, results in a "\%" character in the result. (The complete specification is \%\%.) |

Conversion flag characters

| Flag | Meaning |
| :---: | :--- |
| $\#$ | The value conversion will use the ' ' alternate form". |
| 0 | The conversion will be zero padded. |
| - | The converted value is left adjusted (overrides "-"). |
|  | (a space) A blank should be left before a positive number (or empty string) produced by a signed conversion. |
| + | A sign character ("+" or "-") will precede the conversion (overrides a "space" flag). |

## String templating

Since 2.4 [PEP 292] the string module provides a new mechanism to substitute variables into template strings.
Variables to be substituted begin with a \$. Actual values are provided in a dictionary via the substitute or
safe_substitute methods (substitute throws KeyError if a key is missing while safe_substitute ignores it) :

```
t = string.Template('Hello $name, you won $$$amount') # (note $$ to litteralize $)
t.substitute({'name': 'Eric', 'amount': 100000}) # -> u'Hello Eric, you won $100000'
```

## File objects

(Type file). Created with built-in functions open() [preferred] or its alias file(). May be created by other modules' functions as well.
Unicode file names are now supported for all functions accepting or returning file names (open, os.listdir, etc...).
Operators on file objects

| File operations |  |
| :---: | :---: |
| Operation | Result |
| f.close() | Close file $f$. |
| f.fileno() | Get fileno (fd) for file $f$. |
| f.flush() | Flush file $f$ 's internal buffer. |
| f.isatty() | 1 if file $f$ is connected to a tty-like dev, else 0. |
| f.read([size]) | Read at most size bytes from file $f$ and return as a string object. If size omitted, read to EOF. |
| f.readline() | Read one entire line from file $f$. The returned line has a trailing \n, except possibly at EOF. |
| f.readlines() | Read until EOF with readline() and return a list of lines read. |
| f.xreadlines() | Return a sequence-like object for reading a file line-by-line without reading the entire file into memory. From 2.2, use rather: for line in f (see below). |
| for line in $f$ : do something... | Iterate over the lines of a file (using readline) |
| f.seek(offset[, whence=0]) | ```Set file f's position, like "stdio's fseek()". whence == 0 then use absolute indexing. whence == 1 then offset relative to current pos. whence == 2 then offset relative to file end.``` |
| f.tell() | Return file $f$ 's current position (byte offset). |
| f.write(str) | Write string to file $f$. |
| f.writelines(list) | Write list of strings to file $f$. No EOL are added. |

## File Exceptions

EOFError
End-of-file hit when reading (may be raised many times, e.g. if $f$ is a tty).
IOError
Other I/O-related I/O operation failure

## Sets

Since 2.4, Python has 2 new built-in types with fast C implementations [PEP 218]: set and frozenset (immutable set). Sets are unordered collections of unique (non duplicate) elements. Elements must be hashable. frozensets are hashable (thus can be elements of other sets) while sets are not. All sets are iterable.

Since 2.3, the classes set and Immutableset were available in the module sets. This module remains in the 2.4 std library in addition to the built-in types.

| Main Set operations |  |
| :---: | :---: |
| Operation | Result |
| set/frozenset([iterable=None]) | [using built-in types] Builds a set or frozenset from the given iterable (default: empty), e.g. set([1, 2, 3]), set("hello"). |
| Set/ImmutableSet([iterable=None]) | [using the sets module] Builds a set or Immutableset from the given iterable (default: empty), e.g. Set ([1, 2, 3]). |
| Ien(s) | Cardinality of set $s$. |
| elt in s / not in s | True if element elt belongs / not belongs to set s. |
| for elt in s: process elt... | Iterates on elements of set $s$. |
| s1.issubset(s2) | True if every element in s1 is in s2. |
| s1.issuperset(s2) | True if every element in s2 is in s1. |
| s.add(elt) | Adds element elt to set $s$ (if it doesn't already exist). |
| s.remove(elt) | Removes element elt from set s. KeyError if element not found. |
| s.clear(elt) | Removes all elements from this set (not on immutable sets!). |
| s1.intersection(s2) or s1\&s2 | Returns a new Set with elements common to s1 and s2. |
| s1.union(s2) or s1\|s2 | Returns a new Set with elements from both s1 and s2. |
| s1.difference(s2) or s1-s2 | Returns a new Set with elements in s1 but not in s2. |
| s1.symmetric_difference(s2) or s1^s2 | Returns a new Set with elements in either s1 or s2 but not both. |
| s.copy() | Returns a shallow copy of set $s$. |
| s.update(iterable) | Adds all values from iterable to set s. |

## Advanced Types

- See manuals for more details -

```
- Module objects
```

- Class objects
- Class instance objects
- Type objects (see module: types)
- File objects (see above)
- Slice objects
- Ellipsis object, used by extended slice notation (unique, named Ellipsis)
- Null object (unique, named None)
- XRange objects
- Callable types:
- User-defined (written in Python):
- User-defined Function objects
- User-defined Method objects
o Built-in (written in C):
- Built-in Function objects
- Built-in Method object
- Internal Types:
- Code objects (byte-compile executable Python code: bytecode)
- Frame objects (execution frames)
- Traceback objects (stack trace of an exception)

## Statements

| Statement | Result |
| :---: | :---: |
| pass | Null statement |
| del name[, name]* | Unbind name(s) from object. Object will be indirectly (and automatically) deleted only if no longer referenced. |
| print[>> fileobject,] [s1 [, s2 ]* [,] | Writes to sys.stdout, or to fileobject if supplied. Puts spaces between arguments. Puts newline at end unless statement ends with comma. Print is not required when running interactively, simply typing an expression will print its value, unless the value is None. |
| exec $x$ [in globals [, locals]] | Executes $x$ in namespaces provided. Defaults to current namespaces. $x$ can be a string, file object or a function object. locals can be any mapping type, not only a regular Python dict. |
| callable(value,... [id=value] , [*args], [**kw]) | Call function callable with parameters. Parameters can be passed by name or be omitted if function defines default values. E.g. if callable is defined as "def |
|  | "callable()" <=> "callable(1, 2)" <br> "callable(10)" <=> "callable(10, 2)" <br> "callable(p2=99)" <=> "callable(1, 99)" |
|  | *args is a tuple of positionalarguments. <br> **kw is a dictionary of keyword arguments. |
| yield expression | (Only used within the body of a generator function, outside a try of a try..finally). "Returns" the evaluated expression. |

## Assignment operators

| Assignment operators |  |  |
| :--- | :--- | :---: |
| Operator | Result | Notes |
| $a=b$ | Basic assignment - assign object $b$ to label $a$ | $(1)(2)$ |
| $a+=b$ | Roughly equivalent to $a=a+b$ | $(3)$ |
| $a-=b$ | Roughly equivalent to $a=a-b$ | $(3)$ |
| $a *=b$ | Roughly equivalent to $a=a * b$ | $(3)$ |
| $a /=b$ | Roughly equivalent to $a=a / b$ | $(3)$ |
| $a / /=b$ | Roughly equivalent to $a=a / / b$ | $(3)$ |
| $a \boldsymbol{\%}=b$ | Roughly equivalent to $a=a \% b$ | $(3)$ |
| $a * *=b$ | Roughly equivalent to $a=a * * b$ | $(3)$ |
| $a \&=b$ | Roughly equivalent to $a=a \& b$ | $(3)$ |
| $a \mid=b$ | Roughly equivalent to $a=a \mid b$ | $(3)$ |
| $a \wedge=b$ | Roughly equivalent to $a=a \wedge b$ | $(3)$ |
| $a \gg=b$ | Roughly equivalent to $a=a \gg b$ | $(3)$ |
| $a \ll=b$ | Roughly equivalent to $a=a \ll b$ | $(3)$ |

Notes:

- (1) Can unpack tuples, lists, and strings:
first, second $=1[0: 2] \quad$ \# equivalent to: first=1[0]; second=1[1]
[f, s] = range (2) \# equivalent to: f=0; s=1
$\mathrm{c} 1, \mathrm{c} 2, \mathrm{c} 3=$ 'abc' \# equivalent to: c1='a'; c2='b'; c3='c'
(a, b), c, (d, e, f) = ['ab', 'c', 'def'] \# equivalent to: a='a'; b='b'; c='c'; d='d'; e='e'; f='f'
Tip: $x, y=y, x$ swaps $x$ and $y$.
- (2) Multiple assignment possible:
$11=12=[1,2,3] \quad \# 11$ and 12 points to the same list (11 is 12 )
- (3) Not exactly equivalent - $a$ is evaluated only once. Also, where possible, operation performed in-place $-a$ ismodified rather than replaced.

## Control Flow statements

## Control flow statements

Statement Result

| if condition: <br> suite <br> [elif condition: suite]* <br> [else: <br> suite] | Usual if/else if/else statement |
| :--- | :--- |
| while condition: <br> suite <br> [else: <br> suite] | Usual while statement. The else suite is executed after loop exits, unless the loop is exited with <br> break. |
| for element in sequence: <br> suite <br> [else: <br> suite] | Iterates over sequence, assigning each element to element. Use built-in range function to iterate a <br> number of times. The else suite is executed at end unless loop exited with break. |
| break | Immediately exits for or while loop. |
| continue | Immediately does next iteration of for or while loop. <br> return [result]Exits from function (or method) and returns result (use a tuple to return more than one value). If <br> no result given, then returns None. |

## Exception statements

| Exception statements |  |
| :---: | :---: |
| Statement | Result |
| assert expr[, message] | expr is evaluated. if false, raises exception AssertionError with message. Before 2.3, inhibited if debug is 0 . |
| ```try: suite1 [except [exception [, value]: suite2]+ [else: suite3]``` | Statements in suite1 are executed. If an exception occurs, look in except clause(s) for matching exception. If matches or bare except, execute suite of that clause. If no exception happens, suite in else clause is executed after suite1. If exception has a value, it is put in variable value. exception can also be a tuple of exceptions, e.g. except (KeyError, NameError), val: print val. |
| try: suite1 finally: suite2 | Statements in suite1 are executed. If no exception, execute suite2 (even if suite1 is exited with a return,break or continue statement). If exception did occur, executes suite 2 and then immediately re-raises exception. |
| raise exceptionInstance | Raises an instance of a class derived from Exception (preferred form of raise). |
| raise exceptionClass [, value [, traceback]] | Raises exception of given class exceptionClass with optional value value. Arg traceback specifies a traceback object to use when printing the exception's backtrace. |
| raise | A raise statement without arguments re-raises the last exception raised in the current function. |

- An exception is an instance of an exception class (before 2.0, it may also be a mere string).
- Exception classes must be derived from the predefined class: Exception, e.g.:

```
class TextException(Exception): pass
```

try:
if bad:
raise TextException()
except Exception:
print 'Oops' \# This will be printed because TextException is a subclass of Exception

- When an error message is printed for an unhandled exception, the class name is printed, then a colon and a space, and finally the instance converted to a string using the built-in function str ().
- All built-in exception classes derives from StandardError, itself derived from Exception.

## Name Space Statements

Imported module files must be located in a directory listed in the Python path (sys.path). Since 2.3 , they may reside in a zip file [e.g. sys.path.insert(0, "theZipFile.zip")].

Packages (>1.5): a package is a name space which maps to a directory including module(s) and the special initialization module init .py (possibly empty).
Packages/directories can be nested. You address a module's symbol via [package. [package. . .].module. symbol.
[1.51: On Mac \& Windows, the case of module file names must now match the case as used in the import statement]

| Name space statements | Result |
| :--- | :--- |
| Statement | Imports modules. Members of module must be referred to by qualifying with [package.] <br> module name, e.g.: <br> import module1 [as name1] [, <br> module2]* sys; print sys.argv <br> import package1. subpackage.module <br> package1.subpackage.module. foo () <br> module1 renamed as name1, if supplied. |
| from module import name1 [as <br> othername1][, name2]* | Imports names from module module in current namespace. <br> from sys import argv; print argv <br> from package1 import module; module.foo() <br> from package1. module import foo; foo () |
| name1 renamed as othername1, if supplied. |  |
| [2.4] You can now put parentheses around the list of names in a from module import names |  |
| statement (PEP 328). |  |$|$| Imports all names in module, except those starting with "_". Use sparsely, beware of |
| :--- |
| name clashes! |
| from sys import *; print argv |

|  | from package.module import *; print x <br> Only legal at the top level of a module. If module defines an $\qquad$ all $\qquad$ attribute, only names listed in $\qquad$ all $\qquad$ will be imported. NB: "from package import *" only imports the symbols defined in the package's init__.py file, not those in the package's modules ! |
| :---: | :---: |
| global name1 [, name2] | Names are from global scope (usually meaning from module) rather than local (usually meaning only in function). <br> E.g. in function without global statements, assuming " $x$ " is name that hasn't been used in function or module so far: <br> - Try to read from "x" -> NameError <br> - Try to write to "x" -> creates "x" local to function <br> If " $x$ " not defined in fct, but is in module, then: - Try to read from " $x$ ", gets value from module <br> - Try to write to " x ", creates " x " local to fct <br> But note " $x[0]=3$ " starts with search for " $x$ ", will use to global " $x$ " if no local " $x$ ". |

## Function Definition

```
def func_id ([param_list]):
    suite
```

Creates a function object and binds it to name func_id.

```
param list ::= [id [, id]*]
id ::= value | id = value | *id | **id
```

Args are passed by value. Thus only args representing a mutable object can be modified (are inout parameters). Use a tuple to return more than one value.

Example:
def test (p1, p2 $=5+3$, *args, **kwargs) :

- args with "=" have a default value (evaluated at function definition time).
- If arg list has "*args" then args is assigned a tuple of all remaining non-keywords args passed to the function.
- If list has "**kwargs" then kwargs is assigned a dictionary of all extra arguments passed as keywords.
- args and kwargs are common names but other names may be used as well.

## Class Definition

```
class className [(super_classl[, super_class2]*)]:
    suite
```

Creates a class object and assigns it name className. suite may contain local "defs" of class methods and assignments to class attributes.

## Examples:

class Myclass (class1, class2): ...
Creates a class object inheriting from both class1 and class2. Assigns new class object to name "MyClass". class MyClass: ...
Creates a base class object (inheriting from nothing). Assigns new class object to name "MyClass".
class Myclass (object): ..
Creates a new-style class/type (inheriting from object makes a class a new-style class). Assigns new class object to name "MyClass".

- First arg to class instance methods (operations) is always the target instance object, called 'self' by convention.
- Special method __init__() is called when instance is created.
- Special method ___del__() called when no more reference to object.
- Create instance by "calling" class object, possibly with arg (thus instance=apply(aClassObject, args...) creates an instance!)
- Before 2.2 it was not possible to subclass built-in classes like list, dict (you had to "wrap" them, using UserDict \& UserList modules); since 2.2 you can subclass them directly (see Types/Classes unification).

## Example:

```
class c (c_parent):
    def __init__(self, name):
        self.name = name
    def print name(self):
    print "I'm", self.name
    def call_parent(self):
        c_parent.print_name(self)
```

instance $=c\left(\right.$ 'tom' $\left.^{\prime}\right)$
print instance.name
'tom'
instance.print name()
"I'm tom"

Call parent's super class by accessing parent's method directly and passing "self" explicitly (see "call_parent" in example above).
Many other special methods available for implementing arithmetic operators, sequence, mapping indexing, etc...
Types / classes unification

Base types int, float, str, list, tuple, dict and file now (2.2) behave like classes derived from base class object, and may be subclassed:

```
x = int(2) # built-in cast function now a constructor for base type
y = 3 # <=> int(3) (litterals are instances of new base types)
print type(x), type(y) # int, int
assert isinstance(x, int) # replaces isinstance(x, types.IntType)
assert issubclass(int, object) # base types derive from base class 'object'
s = "hello" # <<> str("hello")
assert isinstance(s, str)
I = 2.3 # <=> float(2.3
class MyInt(int): pass # may subclass base types
x,y = MyInt(1), MyInt("2")
print x, y, x+y # => 1,2,3
class MyList(list): pass
l = MyList("hello")
print l # ['h', 'e', 'l', 'l', 'o']
```

New-style classes extends object.Old-styleclasses don't.

## Documentation Strings

Modules, classes and functions may be documented by placing a string literal by itself as the first statement in the suite. The documentation can be retrieved by getting the $\qquad$ doc .' attribute from the module, class or function.

## Example:

```
class C:
    "A description of C"
        def __init__(self):
            "A description of the constructor"
            # etc.
c.__doc__ == "A description of C"
    c.__init__.__doc__ == "A description of the constructor"
```

## Iterators

- An iterator enumerates elements of a collection. It is an object with a single method next () returning the next element or raising StopIteration.
- You get an iterator on obj via the new built-in function iter (obj), which calls obj. $\qquad$ class $\qquad$ iter $\qquad$
- A collection may be its own iterator by implementing both $\qquad$ iter () and next ().
- Built-in collections (lists, tuples, strings, dict) implement $\qquad$ ter_ ( ) ; dictionaries (maps) enumerate their keys; files enumerates their lines.
- You can build a list or a tuple from an iterator, e.g. list(anIterator)
- Python uses implicitely iterators wherever it has to loop :
- for elt in collection:
- if elt in collection:
- when assigning tuples: $\mathrm{x}, \mathrm{y}, \mathrm{z}=$ collection

## Generators

- A generator is a function that retains its state between 2 calls and produces a new value at each invocation. The values are returned (one at a time) using the keyword yield, while return or raise StopIteration () are used to notify the end of values.
- A typical use is the production of IDs, names, or serial numbers.
- To use a generator: call the generator function to get a generator object, then call generator. next () to get the next value until StopIteration is raised.
- 2.4 introduces generator expressions [PEP 289] similar to list comprehensions, except that they create a generator that will return elements one by one, which is suitable for long sequences :
linkGenerator $=$ (link for link in get_all_links() if not link.followed)
for link in linkGenerator:
...process link...
Generator expressions must appear between parentheses.
- In 2.2, feature needs to be enabled by the statement: from future import generators (not required since 2.3+)

Example:

```
def genID(initialValue=0):
    v = initialValue
    while v < initialValue + 1000:
        yield "ID_%05d" % v
            v += 1
    return # or: raise StopIteration()
generator = genID() # Create a generator
for i in range(10): # Generates 10 values
```

    print generator.next()
    
## Descriptors / Attribute access

- Descriptors are objects implementing at least the first of these 3 methods representing the descriptor protocol:
- $\qquad$ get__ (self, obj, type=None) --> value
- $\qquad$ set__ self, obj, value)
delete (self, obj)
Python now transparently uses descriptors to describe and access the attributes and methods of new-style classes (i.e. derived from object). [more info])
- Built-in descriptors now allow to define:
- Static methods: Use staticmethod (f) to make method $f(x)$ static (unbound).
- Class methods: like a static but takes the Class as 1st argument => Use $f=c l a s s m e t h o d(f)$ to make method $f($ theclass, $x$ ) a class method.
- Properties : A property is an instance of the new built-in type property, which implements the descriptor protocol for attributes => Use propertyName = property (getter=None, setter=None, deleter=None, description=None) to define a property inside or outside a class. Then access it as propertyName or obj.propertyName
- Slots. New style classes can define a class attribute __slots_ to constrain the list of assignable attribute names, to avoid typos (which is normally not detected by Python and leads to the creation of new attributes), e.g. $\qquad$ slots $\qquad$ = ('x', 'y')
Note: According to recent discussions, the real purpose of slots seems still unclear (optimization?), and their use should probably be discouraged.

## Decorators for functions \& methods

- [PEP 318] A decorator $D$ is noted @D on the line preceding the function/method it decorates :
@D
def f(): ...
and is equivalent to:
def f(): ...
$\mathrm{f}=\mathrm{D}(\mathrm{f})$
- Several decorators can be applied in cascade :
@A @B @C
def $f(): .$.
is equivalent to:
$\mathrm{f}=\mathrm{A}(\mathrm{B}(\mathrm{C}(\mathrm{f})))$
- A decorator is just a function taking the fct to be decorated and returns the same function or some new callable thing.
- Decorator functions can take arguments:
@A @B @C(args)
becomes:
def f(): ...
_deco $=C$ (args)
$\overline{\mathrm{f}}=\mathrm{A}(\mathrm{B}(\operatorname{deco}(\mathrm{f})))$
- The decorators @staticmethod and @classmethod replace more elegantly the equivalent declarations $\mathrm{f}=$ staticmethod(f) and $f=$ classmethod(f).

## Misc

```
lambda [param_list]: returnedExpr
```

Creates an anonymous function.
returnedExpr must be an expression, not a statement (e.g., not "if xx:...", "print xxx", etc.) and thus can't contain newlines. Used mostly for filter(), map(), reduce() functions, and GUI callbacks.

## List comprehensions

```
result = [expression for item1 in sequence1 [if conditionl]
        [for item2 in sequence2 ... for itemN in sequenceN]
```

    ]
    
## is equivalent to:

result $=$ []
for item1 in sequencel:
for item2 in sequence2:
for itemN in sequenceN:
if (conditionl) and further conditions:
result.append (expression)

## Nested scopes

Since 2.2 nested scopes no longer need to be specially enabled by a from __future__ import nested_scopes directive, and are always used.

## Built-In Functions

| Built-In Functions | Result |
| :--- | :--- |
| Function | Imports module within the given context (see library reference for more details) |
| globals[,locals[,from <br> glist]]]) | Returns the absolute value of the number $x$. |
| abs $(x)$ | Calls func/method $f$ with arguments args and optional keywords. |
| apply $(f$, args[, <br> keywords $])$ | Returns a Buffer from a slice of object, which must support the buffer call interface (string, array, <br> buffer). <br> bize $]])$ |
| Callable $(x)$ | Returns True if $x$ callable, else False. |

| $\mathbf{~ c h r ~}(i)$ | Returns one-character string whose ASCII code isinteger i. |
| :---: | :---: |
| classmethod(function) | Returns a class method for function. A class method receives the class as implicit first argument, just like an instance method receives the instance. To declare a class method, use this idiom: ```class C: def f(cls, arg1, arg2, ...): ... f = classmethod(f)``` <br> Then call it on the class $C . f()$ or on an instance $C() . f()$. The instance is ignored except for its class. If a class method is called for a derived class, the derived class object is passed as the implied first argument. <br> Since 2.4 you can alternatively use the decorator notation: <br> class C: $\quad$ @classmethod <br> def $f(c l s, ~ a r g 1, ~ a r g 2, ~ . .):. ~ . . . ~$ |
| $\mathbf{c m p}(x, y)$ | Returns negative, 0 , positive if $x<,==$, $>$ to $y$ respectively. |
| coerce ( $x, y$ ) | Returns a tuple of the two numeric arguments converted to a common type. |
| compile(string, filename, kind[, flags[, dont_inherit]]) | Compiles string into a code object. filename is used in error message, can be any string. It is usually the file from which the code was read, or eg. '<string>' if not read from file. kind can be 'eval' if string is a single stmt, or 'single' which prints the output of expression statements that evaluate to something else than None, or be 'exec'. New args flags and dont_inherit concern future statements. |
| complex(rea/[, image]) | Creates a complex object (can also be done using J or $\mathbf{j}$ suffix, e.g. 1+3J). |
| delattr(obj, name) | Deletes the attribute named name of object obj <=> del obj. name |
| dict([mapping-orsequence]) | Returns a new dictionary initialized from the optional argument (or an empty dictionary if no argument). Argument may be a sequence (or anything iterable) of pairs (key,value). |
| $\mathbf{d i r}([o b j e c t])$ | Without args, returns the list of names in the current local symbol table. With a module, class or class instance object as arg, returns the list of names in its attr. dictionary. |
| divmod( $a, b$ ) | Returns tuple ( $a / b, a \% b$ ) |
| enumerate(iterable) | Iterator returning pairs (index, value) of iterable, e.g. List (enumerate('Py')) -> [(0, 'P'), (1, 'y')]. |
| ```eval(s[, globals[, locals]])``` | Evaluate string $s$ in (optional) globals, locals contexts. $s$ must have no NUL's or newlines. $s$ can also be a code object. locals can be any mapping type, not only a regular Python dict. Example: $x=1 ; \text { assert eval ('x + 1') == } 2$ |
| execfile(file[, globals [,locals]]) | Executes a file without creating a new module, unlike import. locals can be any mapping type, not only a regular Python dict. |
| file(filename[,mode [,bufsize]]) | Opens a file and returns a new file object. Alias for open. |
| filter(function,sequence) | Constructs a list from those elements of sequence for which function returns true. function takes one parameter. |
| float ( $x$ ) | Converts a number or a string to floating point. |
| getattr(object,name [,default])) | Gets attribute called name from object, e.g. getattr(x, 'f') <=> x.f). If not found, raises AttributeError or returns default if specified. |
| globals() | Returns a dictionary containing the current global variables. |
| hasattr(object, name) | Returns true if object has an attribute called name. |
| hash(object) | Returns the hash value of the object (if it has one). |
| help([object]) | Invokes the built-in help system. No argument -> interactive help; if object is a string (name of a module, function, class, method, keyword, or documentation topic), a help page is printed on the console; otherwise a help page on object is generated. |
| hex( $x$ ) | Converts a number $x$ to a hexadecimal string. |
| id(object) | Returns a unique integer identifier for object. |
| input([prompt]) | Prints prompt if given. Reads input and evaluates it. Uses line editing / history if module readline available. |
| int( $x$ [, base]) | Converts a number or a string to a plain integer. Optional base parameter specifies base from which to convert string values. |
| intern(aString) | Enters aString in the table of interned strings and returns the string. Before 2.3, interned strings were 'immortals' (never garbage collected). This is no longer true in 2.3+. |
| isinstance $(o b j$, classInfo) | Returns true if obj is an instance of class classInfo or an object of type classInfo (classInfo may also be a tuple of classes or types). If issubclass ( $A, B$ ) then isinstance ( $x, A$ ) $=>$ isinstance ( $x, B$ ) |
| $\begin{aligned} & \text { issubclass(class1, } \\ & \text { class2) } \\ & \hline \end{aligned}$ | Returns true if class1 is derived from class2 (or if class1 is class2). |
| iter(obj[,sentine/]) | Returns an iterator on obj. If sentinel is absent, obj must be a collection implementing either iter_() or getitem_ (). If sentinel is given, obj will be called with no arg; if the value returned is equal to sentinel, StopIteration will be raised, otherwise the value will be returned. See Iterators. |
| Ien(obj) | Returns the length (the number of items) of an object (sequence, dictionary, or instance of class implementing __len__). |
| list([seq]) | Creates an empty list or a list with same elements as seq. seq may be a sequence, a container that supports iteration, or an iterator object. If seq is already a list, returns a copy of it. |
| locals() | Returns a dictionary containing current local variables. |
| long(x[, base]) | Converts a number or a string to a long integer. Optional base parameter specifies the base from which to convert string values. |
| $\boldsymbol{m a p}$ (function, list, ...) | Applies function to every item of list and returns a list of the results. If additional arguments are passed, function must take that many arguments and they are given to function on each call. |
| $\boldsymbol{m a x}($ seq[, args...]) | With a single argument seq, returns the largest item of a non-empty sequence (such as a string, tuple or list). With more than one argument, returns the largest of the arguments. |
| $\boldsymbol{\operatorname { m i n }}$ (seq[, args...]) | With a single argument seq, returns the smallest item of a non-empty sequence (such as a string, tuple or list). With more than one argument, returns the smallest of the arguments. |
| oct ( $x$ ) | Converts a number to an octal string. |
| open(filename [, mode='r', [bufsize]]) | Returns a new file object. See also alias file(). Use codecs.open() instead to open an encoded file and provide transparent encoding / decoding. <br> - filename is the file name to be opened <br> - mode indicates how the file is to be opened: <br> - 'r' for reading |

|  | - 'w' for writing (truncating an existing file) 'a' opens it for appending ' + ' (appended to any of the previous modes) open the file for updating (note that 'w+'truncates the file) <br> - 'b' (appended to any of the previous modes) open the file in binary mode 'U' (or 'rU') open the file for reading in Universal Newline mode: all variants of EOL (CR, LF, CR+LF) will be translated to a single LF ('\n'). <br> - bufsize is 0 for unbuffered, 1 for line-buffered, negative for sys-default, all else, of (about) given size. |
| :---: | :---: |
| ord(c) | Returns integer ASCII value of $c$ (a string of len 1). Works with Unicode char. |
| pow $(x, y[, z])$ | Returns $x$ to power $y$ [modulo z]. See also ** operator. |
| ```range(start [,end [, step]])``` | Returns list of ints from >= start and < end. <br> With 1 arg, list from 0..arg-1 <br> With 2 args, list from start..end-1 <br> With 3 args, list from start up to end by step |
| raw_input([prompt]) | Prints prompt if given, then reads string from std input (no trailing \n). See also input(). |
| reduce(f, list [, init]) | Applies the binary function $f$ to the items of list so as to reduce the list to a single value. If init is given, it is "prepended" to list. |
| reload(module) | Re-parses and re-initializes an already imported module. Useful in interactive mode, if you want to reload a module after fixing it. If module was syntactically correct but had an error in initialization, must import it one more time before calling reload(). |
| $\mathbf{r e p r}$ (object) | Returns a string containing a printable and if possible evaluable representation of an object. <=> `object` (using backquotes). Class redefinable (_repr__). See also str() |
| round ( $x, n=0$ ) | Returns the floating point value $x$ rounded to $n$ digits after the decimal point. |
| setattr(object, name, value) | This is the counterpart of getattr().setattr(o, 'foobar', 3) <=> o.foobar = 3 . Creates attribute if it doesn't exist! |
| ```slice([start,] stop[, step])``` | Returns a slice object representing a range, with R/O attributes: start, stop, step. |
| staticmethod(function) | Returns a static method for function. A static method does not receive an implicit first argument. To declare a static method, use this idiom: ```class C: def f(arg1, arg2, ...): ... f = staticmethod(f)``` <br> Then call it on the class $C . f()$ or on an instance $C() . f()$. The instance is ignored except for its class. Since 2.4 you can alternatively use the decorator notation: <br> class C: <br> @staticmethod <br> def f(cls, arg1, arg2, ...): ... |
| str(object) | Returns a string containing a nicely printable representation of an object. Class overridable (__str__). See also repr(). |
| sum(iterable[, start=0]) | Returns the sum of a sequence of numbers (not strings), plus the value of parameter. Returns start when the sequence is empty. |
| ```super( type[, object-or- type])``` | Returns the superclass of type. If the second argument is omitted the super object returned is unbound. If the second argument is an object, isinstance (obj, type) must be true. If the second argument is a type, issubclass (type2, type) must be true. Typical use: <br> class C(B): <br> def meth(self, arg): <br> super (C, self).meth(arg) |
| tuple([seq]) | Creates an empty tuple or a tuple with same elements as seq. seq may be a sequence, a container that supports iteration, or an iterator object. If seq is already a tuple, returns itself (not a copy). |
| type(obj) | Returns a type object [see module types] representing the type of obj. Example: import types if type $(x)==$ types.StringType: print 'It is a string'. NB: it is better to use instead: if isinstance $(x$, types.StringType)... |
| unichr(code) | Returns a unicode string 1 char long with given code. |
| unicode(string[, encoding[,error]]]) | Creates a Unicode string from a 8-bit string, using the given encoding name and error treatment ('strict', 'ignore',or 'replace'\}. For objects which provide a __unicode__ () method, it will call this method without arguments to create a Unicode string. |
| vars([object]) | Without arguments, returns a dictionary corresponding to the current local symbol table. With a module, class or class instance object as argument, returns a dictionary corresponding to the object's symbol table. Useful with the "\%" string formatting operator. |
| ```xrange(start [, end [, step]])``` | Like range(), but doesn't actually store entire list all at once. Good to use in "for" loops when there is a big range and little memory. |
| zip(seq1[,seq2,...]) | Returns a list of tuples where each tuple contains the $n$th element of each of the argument sequences. Since 2.4 returns an empty list if called with no arguments (was raising TypeError before). |

## Built-In Exception classes

## Exception

The mother of all exceptions. exception.args is a tuple of the arguments passed to the constructor.

- StopIteration

Raised by an iterator's next () method to signal that there are no further values.

- SystemExit

On sys.exit()

- Warning

Base class for warnings (see module warning)

- UserWarning

Warning generated by user code.

- PendingDeprecationWarning
- DeprecationWarning

Warning about deprecated code.

- SyntaxWarning

Warning about dubious syntax.

- RuntimeWarning

Warning about dubious runtime behavior

- StandardError

Base class for all built-in exceptions; derived from Exception root class.

- ArithmeticError

Base class for arithmetic errors

- FloatingPointError

When a floating point operation fails.
. OverflowError
On excessively large arithmetic operation.

- ZeroDivisionError

On division or modulo operation with 0 as 2 nd argument.

- AssertionError

When an assert statement fails

- AttributeError

On attribute reference or assignment failure

- EnvironmentError [new in 1.5.2]

On error outside Python; error arg. tuple is (errno, errMsg...)

- IOError [changed in 1.5.2]

I/O-related operation failure.

- OSError [new in 1.5.2]

Used by the os module's os.error exception.

- WindowsError

When a Windows-specific error occurs or when the error number does not correspond to an errno value.

- EOFError

Immediate end-of-file hit by input() or raw_input()

- ImportError

On failure of import to find module or name.

- KeyboardInterrupt

On user entry of the interrupt key (often `CTRL-C')

- LookupError
base class for IndexError, KeyError
- IndexError

On out-of-range sequence subscript

- KeyError

On reference to a non-existent mapping (dict) key

- MemoryError

On recoverable memory exhaustion

- NameError

On failure to find a local or global (unqualified) name.

## o UnboundLocalError

On reference to an unassigned local variable.

- ReferenceError

On attempt to access to a garbage-collected object via a weak reference proxy.

- RuntimeError

Obsolete catch-all; define a suitable error instead.
○ NotImplementedError [new in 1.5.2]
On method not implemented.

- SyntaxError

On parser encountering a syntax error

## - IndentationError

On parser encountering an indentation syntax error

- TabError

On parser encountering an indentation syntax error

- SystemError

On non-fatal interpreter error - bug - report it

- TypeError

On passing inappropriate type to built-in operator or function.

- ValueError

On argument error not covered by TypeError or more precise.

- UnicodeError

On Unicode-related encoding or decoding error.

## Standard methods \& operators redefinition in classes

Standard methods \& operators map to special methods '__method__' and thus can be redefined (mostly in user-defined classes), e.g.:
class C:
def __init__(self, V$)$ : self.value $=\mathrm{v}$
def __add_(self, r): return self.value $+r$
$a=C(3)$ \# sort of like calling $C$. init (a, 3)

| Special methods for any class |  |
| :---: | :---: |
| Method | Description |
| init__(self, args) | Instance initialization (on construction) |
| del___(self) | Called on object demise (refcount becomes 0) |
| __repr__(self) | repr() and '... conversions |
| __str__(self) | str () and print statement |
| cmp__(self,other) | Compares self to other and returns <0, 0 , or >0. Implements >, <, = = etc... |
| It__(self, other) | Called for self < other comparisons. Can return anything, or can raise an exception. |
| le___(self, other) | Called for self <= other comparisons. Can return anything, or can raise an exception. |
| gt__(self, other) | Called for self > other comparisons. Can return anything, or can raise an exception. |
| ge__(self, other) | Called for self > = other comparisons. Can return anything, or can raise an exception. |
| eq__(self, other) | Called for self $==$ other comparisons. Can return anything, or can raise an exception. |
| __ne__(self, other) | Called for self ! = other (and self <> other) comparisons. Can return anything, or can raise an exception. |
| hash__(self) | Compute a 32 bit hash code; hash() and dictionary ops |
| _nonzero__(self) | Returns 0 or 1 for truth value testing. when this method is not defined, __ len__ () is called if defined; otherwise all class instances are considered "true". |
| getattr__(self,name) | Called when attribute lookup doesn't find name. See also __getattribute |
| getattribute__( self, name) | Same as __getattr__ but always called whenever the attribute name is accessed. |
| _setattr__(self, name, value) | Called when setting an attribute (inside, don't use "self.name = value", use instead "self.__dict__[name] = value") |
| delattr__(self, name) | Called to delete attribute <name>. |
| __call__(self, *args, **kwargs) | Called when an instance is called as function: obj (arg1, $\arg 2, \ldots$ ) is a shorthand for obj. __call__(arg1, arg2, ...). |

## Operators

See list in the operator module. Operator function names are provided with $\mathbf{2}$ variants, with or without leading \& trailing '__' (e.g. __ add___ or add).

| Numeric operations special methods |  |
| :---: | :---: |
| Operator | Special method |
| self + other | _add___(self, other) |
| self - other | _sub__(self, other) |
| self * other | _mul__(self, other) |
| self / other | div__(self, other) or __truediv__(self,other) if __future__.division is active. |
| self / / other | floordiv__(self, other) |
| self \% other | mod___(self, other) |
| divmod(self,other) | divmod__(self, other) |
| self ** other | _pow__(self, other) |
| self \& other | _and___(self, other) |
| self ^ other | xor___(self, other) |
| self \| other | or__(self, other) |
| self << other | Ishift__(self, other) |
| self $\gg$ other | _rshift__(self, other) |
| nonzero(self) | nonzero__(self) (used in boolean testing) |
| -self | neg__(self) |
| +self | _pos___(self) |
| abs(self) | _abs___(self) |
| ~self | _invert__(self) (bitwise) |
| self $\mathbf{+}=$ other | _iadd___(self, other) |
| self $=$ = other | isub__(self, other) |
| self $*=$ other | _imul___(self, other) |
| self /= other | _idiv__(self, other) or __itruediv__(self,other) if __future__. division is in effect. |
| self //= other | ifloordiv__(self, other) |
| self \%= other | _imod__(self, other) |
| self $* *=$ other | _ipow__(self, other) |
| self $\boldsymbol{\&}=$ other | _iand___(self, other) |
| self ^ = other | ixor__(self, other) |
| self I = other | _ior__(self, other) |
| self <<= other | _ilshift__(self, other) |
| self $\gg=$ other | _irshift__(self, other) |

| Conversions |  |
| :---: | :---: |
| built-in function | Special method |
| int(self) | int__(self) |
| long(self) | long__(self) |
| float(self) | float__(self) |
| complex(self) | complex__(self) |
| oct(self) | oct__(self) |
| hex(self) | hex__(self) |
| coerce(self, other) | coerce___ (self, ot |

Right-hand-side equivalents for all binary operators exist; they are called when class instance is on r-h-s of operator:

- $a+3$ calls __add__(a, 3)

```
- 3 + a calls radd (a, 3)
```

| Special operations for containers |  |  |
| :---: | :---: | :---: |
| Operation | Special method | Notes |
| All sequences and maps: |  |  |
| Ien(self) | _len__(self) | length of object, $>=0$. Length $0==$ false |
| self[ $k$ ] | __getitem__(self, k) | Get element at indice /key k (indice starts at 0 ). Or, if $k$ is a slice object, return a slice. |
| self[k] = value | setitem__(self, $k$, value) | Set element at indice/key/slice $k$. |
| del self[k] | delitem___(self, k) | Delete element at indice/key/slice $k$. |
| elt in self elt not in self | $\begin{aligned} & \text { _contains__(self, elt) } \\ & \text { not__contains__(self, elt) } \end{aligned}$ | More efficient than std iteration thru sequence. |
| iter(self) | __iter__(se/f) __ | Returns an iterator on elements (keys for mappings <=> self.iterkeys()). See iterators. |
| Sequences, general methods, plus: |  |  |
| self[i:j] | __getslice__(self, $i, j$ ) | Deprecated since 2.0 , replaced by $\qquad$ getitem $\qquad$ with a slice object as parameter. |
| self[ $\mathrm{i}: \mathrm{j}]=$ seq | __setslice__(self, $i, j, s e q)$ | Deprecated since 2.0 , replaced by $\qquad$ setitem $\qquad$ with a slice object as parameter. |
| del self[i:j] | __delslice__(self, $i, j$ ) | Same as self[i:j] = [] - Deprecated since 2.0, replaced by __delitem with a slice object as parameter. |
| self * $n$ | repeat__(self, $n$ ) |  |
| self + other | concat__(self, other) |  |
| Mappings, general methods, plus: |  |  |
| hash(self) | __hash__(self) | hashed value of object self is used for dictionary keys |

## Special informative state attributes for some types:

Tip: use module inspect to inspect live objects.

| Lists \& Dictionaries |  |
| :--- | :--- |
| Attribute | Meaning |
| Metheds_ | (list, R/O): list of method names-of the object Deprecated, use dir () instead |

| Modules |  |
| :---: | :---: |
| Attribute | Meaning |
| doc | (string/None, R/O): doc string (<=> __dict _ ['__doc _ ']) |
| name | (string, R/O): module name (also in __dict _ ['__name__']) |
| dict | (dict, $\mathrm{R} / \mathrm{O}$ ): module's name space |
| file | (string/undefined, R/O): pathname of .pyc, .pyo or .pyd (undef for modules statically linked to the interpreter) |
| path | (list/undefined, R/W): List of directory paths where to find the package (for packages only). |

| Classes |  |
| :---: | :---: |
| Attribute | Meaning |
| doc | (string/None, R/W): doc string (<=> __dict__['_doc__']) |
| name | (string, R/W): class name (also in __dict__['__name__']) |
| bases | (tuple, R/W) : parent classes |
| dict | (dict, R/W): attributes (class name space) |

| Instances |  |
| :--- | :--- |
| Attribute | Meaning |
| _class_- | (class, R/W): instance's class |
| dict__ | (dict, R/W): attributes |

| Ser defined fun |  |
| :---: | :---: |
| Attribute | Meaning |
| doc | (string/None, R/W): doc string |
| name | (string, R/O): function name |
| func_doc | (R/W): same as __doc |
| func_name | (R/O, R/W from 2.4): same as _name |
| func_defaults | (tuple/None, R/W): default args values if any |
| func_code | (code, R/W): code object representing the compiled function body |
| func_globals | (dict, R/O): ref to dictionary of func global variables |

| User-defined Methods |  |
| :--- | :--- |
| Attribute | Meaning |
| _doc_ | (string/None, R/O): doc string |
| _name_- | (string, R/O): method name (same as im_func.__name__) |
| im_class | (class, R/O): class defining the method (may be a base class) |
| im_self | (instance/None, R/O): target instance object (None if unbound) |
| im_func | (function, R/O): function object |

| Built-in Functions \& methods |  |
| :--- | :--- |
| Attribute | Meaning |
| _doc_ | (string/None, R/O): doc string |
| __name_ | (string, R/O): function name |
| self_ | [methods only] target object |

| [members= |  |
| :---: | :---: |
| Codes |  |
| Attribute | Meaning |
| co_name | (string, R/O): function name |
| co_argcount | (int, R/0): number of positional args |
| co_nlocals | (int, R/O): number of local vars (including args) |
| co_varnames | (tuple, R/O): names of local vars (starting with args) |
| co_code | (string, R/O): sequence of bytecode instructions |
| co_consts | (tuple, R/O): literals used by the bytecode, 1st one is function doc (or None) |
| co_names | (tuple, R/O): names used by the bytecode |
| co_filename | (string, R/O): filename from which the code was compiled |
| co_firstlineno | (int, R/O): first line number of the function |
| co_Inotab | (string, R/O): string encoding bytecode offsets to line numbers. |
| co_stacksize | (int, R/O): required stack size (including local vars) |
| co_flags | (int, R/O): flags for the interpreter bit 2 set if fct uses "*arg" syntax, bit 3 set if fct uses '**keywords' syntax |

| Frames |  |
| :--- | :--- |
| Attribute | Meaning |
| f_back | (frame/None, R/O): previous stack frame (toward the caller) |
| f_code | (code, R/O): code object being executed in this frame |
| f_locals | (dict, R/O): local vars |
| f_globals | (dict, R/O): global vars |
| f_builtins | (dict, R/O): built-in (intrinsic) names |
| f_restricted | (int, R/O): flag indicating whether fct is executed in restricted mode |
| f_lineno | (int, R/O): current line number |
| f_lasti | (int, R/O): precise instruction (index into bytecode) |
| f_trace | (function/None, R/W): debug hook called at start of each source line |
| f_exc_type | (Type/None, R/W): Most recent exception type |
| f_exc_value | (any, R/W): Most recent exception value |
| f_exc_traceback | (traceback/None, R/W): Most recent exception traceback |

Tracebacks
Attribute Meaning
tb_next (frame/None, R/O): next level in stack trace (toward the frame where the exception occurred)
tb_frame (frame, R/O): execution frame of the current level
tb_lineno (int, R/O): line number where the exception occured
tb_lasti (int, R/O): precise instruction (index into bytecode)

| Slices |  |
| :--- | :--- |
| Attribute | Meaning |
| start | (any/None, R/O): lowerbound, included |
| stop | (any/None, R/O): upperbound, excluded |
| step | $($ any/None, R/O): step value |

| Complex numbers |  |
| :--- | :--- |
| Attribute | Meaning |
| real | (float, R/O): real part |
| imag | (float, R/O): imaginary part |

xranges
Attribute Meaning
tolist (Built-in method, R/O): ?

## Important Modules

sys
System-specific parameters and functions. [Full doc]

| Some sys variables | Content |
| :--- | :--- |
| Variable | The list of command line arguments passed to a Python script. sys.argv [0] is the script name. |
| argv | A list of strings giving the names of all modules written in C that are linked into this interpreter. |
| builtin_module_names | Native byte order, either 'big'(-endian) or 'little'(-endian). |
| byteorder | How often to check for thread switches or signals (measured in number of virtual machine <br> instructions) |
| check_interval | A string containing the copyright pertaining to the Python interpreter. |
| copyright | Root directory where platform-dependent Python files are installed, e.g. 'C: |
| Python23', '/usr'. |  |
| exec_prefix <br> prefix | Name of executable binary of the Python interpreter (e.g. 'C: $\backslash \backslash P y t h o n 23 \backslash \backslash p y t h o n . e x e ', ~$ <br> '/usr/bin/python') |
| executable | User can set to a parameterless function. It will get called before interpreter exits. Deprecated since <br> 2.4. Code should be using the existing atexit module |
| exitfunc | Set only when an exception not handled and interpreter prints an error. Used by debuggers. |
| last_type, last_value, <br> last_traceback | Maximum positive value for integers. Since 2.2 integers and long integers are unified, thus integers |
| maxint |  |

|  | have no limit. |
| :---: | :---: |
| maxunicode | Largest supported code point for a Unicode character. |
| modules | Dictionary of modules that have already been loaded. |
| path | Search path for external modules. Can be modified by program. sys.path $[0]==$ directory of script currently executed. |
| platform | The current platform, e.g. "sunos5", "win32" |
| ps1, ps2 | Prompts to use in interactive mode, normally ">>>" and "..." |
| stdin, stdout, stderr | File objects used for I/O. One can redirect by assigning a new file object to them (or any object: with a method $\qquad$ for stdout/stderr, or with a method readline () for stdin). stdin__ stdout and _stderr are the default values. |
| version | String containing version info about Python interpreter. |
| version_info | Tuple containing Python version info - (major, minor, micro, level, serial). |
| winver | Version number used to form registry keys on Windows platforms (e.g. '2.2'). |
| Some sys functions |  |
| Function | Result |
| displayhook | The function used to display the output of commands issued in interactive mode - defaults to the builtin $\qquad$ displayhook is the original value. |
| excepthook | Can be set to a user defined function, to which any uncaught exceptions are passed. excepthook is the original value. |
| exit( $n$ ) | Exits with status $n$ (usually 0 means OK). Raises SystemExit exception (hence can be caught and ignored by program) |
| getrefcount(object) | Returns the reference count of the object. Generally 1 higher than you might expect, because of object arg temp reference. |
| setcheckinterval(interval) | Sets the interpreter's thread switching interval (in number of bytecode instructions, default: 10 until 2.2, 100 from 2.3). |
| settrace(func) | Sets a trace function: called before each line of code is exited. |
| setprofile(func) | Sets a profile function for performance profiling. |
| exc_info() | Info on exception currently being handled; this is a tuple (exc_type, exc_value, exc_traceback). Warning: assigning the traceback return value to a local variable in a function handling an exception will cause a circular reference. |
| setdefaultencoding(encoding) | ) Change default Unicode encoding - defaults to 7-bit ASCII. |
| getrecursionlimit() | Retrieve maximum recursion depth. |
| setrecursionlimit() | Set maximum recursion depth (default 1000). |

## 0 S

Miscellaneous operating system interfaces. [Full doc]
"synonym" for whatever OS-specific module (nt, mac, posix...) is proper for current environment. This module uses posix whenever possible.
(see also M.A. Lemburg's utility platform.py (now included in 2.3+)

| Some os variables |  |
| :--- | :--- |
| Variable | Meaning |
| name | name of O/S-specific module (e.g. "posix", "mac", "nt") |
| path | O/S-specific module for path manipulations. <br> On Unix, os.path. split () <=> posixpath. split () |
| curdir | string used to represent current directory (eg '.') |
| pardir | string used to represent parent directory (eg '..') |
| sep | string used to separate directories ('/' or ''\'). Tip: Use os.path. join () to build portable paths. |
| altsep | Alternate separator if applicable (None otherwise) |
| pathsep | character used to separate search path components (as in \$PATH), eg. ';' for windows. |
| linesep | line separator as used in text files, ie '\n' on Unix, '\r\n' on Dos/Win, '\r' on Mac. |

| Some os functions | Result |
| :--- | :--- |
| Function | Recursive directory creation (create required intermediary dirs); os.error if <br> fails. |
| removedirs(path) | Recursive directory delete (delete intermediary empty dirs); fails (os.error) if <br> the directories are not empty. |
| renames(old, new) | Recursive directory or file renaming; os.error if fails. |
| urandom( $n$ ) | Returns a string containing $n$ bytes of random data. |

## posix

Posix OS interfaces. [Full doc]
Do not import this module directly, import os instead! (see also module: shutil for file copy \& remove functions)

| posix Variables |  |
| :--- | :--- |
| Variable | Meaning |
| environ | dictionary of environment variables, e.g. posix.environ['HOME']. |
| error | exception raised on POSIX-related error. <br> Corresponding value is tuple of errno code and perror() string. |

| Some posix functions |  |
| :--- | :--- |
| Function | Result |
| chdir(path) | Changes current directory to path. |
| chmod(path, mode) | Changes the mode of path to the numeric mode |

| close( $f d$ ) | Closes file descriptor $f d$ opened with posix.open. |
| :---: | :---: |
| _exit( $n$ ) | Immediate exit, with no cleanups, no SystemExit, etc... Should use this to exit a child process. |
| $\operatorname{execv}(p, \operatorname{args})$ | "Become" executable $p$ with args args |
| getcwd() | Returns a string representing the current working directory. |
| getcwdu() | Returns a Unicode string representing the current working directory. |
| getpid() | Returns the current process id. |
| getsid() | Calls the system call getsid() [Unix]. |
| fork() | Like C's fork(). Returns 0 to child, child pid to parent [Not on Windows]. |
| kill(pid, signal) | Like C's kill [Not on Windows]. |
| listdir(path) | Lists (base)names of entries in directory path, excluding '.' and '..'. If path is a Unicode string, so will be the returned strings. |
| Iseek(fd, pos, how) | Sets current position in file fd to position pos, expressed as an offset relative to beginning of file (how=0), to current position (how=1), or to end of file (how=2). |
| mkdir(path[, mode]) | Creates a directory named path with numeric mode (default 0777). |
| open(file, flags, mode) | Like C's open(). Returns file descriptor. Use file object functions rather than this low level ones. |
| pipe() | Creates a pipe. Returns pair of file descriptors (r,w) [Not on Windows]. |
| ```popen(command, mode='r', bufSize=0)``` | Opens a pipe to or from command. Result is a file object to read to or write from, as indicated by mode being 'r' or ' $w$ '. Use it to catch a command output ('r' mode), or to feed it ('w' mode). |
| remove(path) | See unlink. |
| rename(old, new) | Renames/moves the file or directory old to new. [error if target name already exists] |
| renames(old, new) | Recursive directory or file renaming function. Works like rename(), except creation of any intermediate directories needed to make the new pathname good is attempted first. After the rename, directories corresponding to rightmost path segments of the old name will be pruned away using removedirs(). |
| rmdir(path) | Removes the empty directory path |
| $\operatorname{read}(f d, n)$ | Reads $n$ bytes from file descriptor $f d$ and return as string. |
| stat(path) | Returns st_mode, st_ino, st_dev, st_nlink, st_uid,st_gid, st_size, st_atime, st_mtime, st_ctime. [st_ino, st_uid, st_gid are dummy on Windows] |
| system(command) | Executes string command in a subshell. Returns exit status of subshell (usually 0 means OK). Since 2.4 use subprocess.call() instead. |
| times() | Returns accumulated CPU times in sec (user, system, children's user, children's sys, elapsed real time) [3 last not on Windows]. |
| unlink(path) | Unlinks ("deletes") the file (not dir!) path. Same as: remove. |
| utime(path, (aTime, mTime)) | Sets the access \& modified time of the file to the given tuple of values. |
| wait() | Waits for child process completion. Returns tuple of pid, exit_status [Not on Windows]. |
| waitpid(pid, options) | Waits for process pid to complete. Returns tuple of pid, exit_status [Not on Windows]. |
| write(fd, str) | Writes str to file fd. Returns nb of bytes written. |

## posixpath

Posix pathname operations
Do not import this module directly, import os instead and refer to this module as os.path. (e.g. os.path.exists (p))!

| Function | Result |
| :---: | :---: |
| abspath(p) | Returns absolute path for path $p$, taking current working dir in account. |
| commonprefix(list) | Returns the longuest path prefix (taken character-by-character) that is a prefix of all paths in list (or " if list empty). |
| dirname/basename (p) | directory and name parts of the path $p$. See also split. |
| exists(p) | True if string $p$ is an existing path (file or directory). See also lexists. |
| expanduser ( $p$ ) | Returns string that is (a copy of) $p$ with " $\sim$ " expansion done. |
| expandvars( $p$ ) | Returns string that is (a copy of) $p$ with environment vars expanded. [Windows: case significant; must use Unix: \$var notation, not \%var\%] |
| getmtime(filepath) | Returns last modification time of filepath (integer nb of seconds since epoch). |
| getatime(filepath) | Returns last access time of filepath (integer nb of seconds since epoch). |
| getsize(filepath) | Returns the size in bytes of filepath. os.error if file inexistent or inaccessible. |
| isabs(p) | True if string $p$ is an absolute path. |
| isdir(p) | True if string $p$ is a directory. |
| islink(p) | True if string $p$ is a symbolic link. |
| ismount ( $p$ ) | True if string $p$ is a mount point [true for all dirs on Windows]. |
| join( $p[, q[, \ldots]])$ | Joins one or more path components intelligently. |
| lexists(path) | True if the file specified by path exists, whether or not it's a symbolic link (unlike exists). |
| split(p) | Splits $p$ into (head, tail) where tail is last pathname component and head is everything leading up to that. $<=>$ (dirname (p), basename (p)) |
| splitdrive( $p$ ) | Splits path $p$ in a pair ('drive:', tail) [Windows] |
| splitext( $p$ ) | Splits into (root, ext) where last comp of root contains no periods and ext is empty or starts with a period. |
| walk( $p$, visit, arg) | Calls the function visit with arguments (arg, dirname, names) for each directory recursively in the directory tree rooted at $p$ (including $p$ itself if it's a dir). The argument dirname specifies the visited directory, the argument names lists the files in the directory. The visit function may modify names to influence the set of directories visited below dirname, e.g. to avoid visiting certain parts of the tree. |

## shutil

High-level file operations (copying, deleting). [Full doc]

| Main shutil functions | Result |
| :--- | :--- |
| Function | Copies the contents of file src to file dest, retaining file permissions. |
| copy(src, dest) | Recursively copies an entire directory tree rooted at src into dest (which should not <br> already exist). If symlinks is true, links in src are kept as such in dest. |
| move(src, dest) | Recursively moves a file or directory to a new location. |
| rmtree(path[, ignore_errors[, onerror]]) | Deletes an entire directory tree, ignoring errors if ignore_errors is true, or calling <br> onerror(func, path, sys.exc_info()) if supplied, with arguments func (faulty function), <br> and path (concerned file). |

(and also: copyfile, copymode, copystat, copy2)

## time

Time access and conversions. [Full doc]

## Variables

## Variable Meaning

altzone Signed offset of local DST timezone in sec west of the Oth meridian. daylight Non zero if a DST timezone is specified.

| Some functions | Result |
| :--- | :--- |
| Function | Returns a float representing UTC time in seconds since the epoch. |
| time() | Returns a tuple representing time : (year aaaa, month(1-12), day(1-31), hour(0-23), minute(0- <br> 59), second(0-59), weekday(0-6, 0 is monday), Julian day(1-366), daylight flag(-1,0 or 1)). |
| gmtime(secs), localtime(secs) | 24-character string of the following form: 'Sun Jun 20 23:21:05 1993'. |
| asctime(timeTuple), | Returns a formated string representing time. See format in table below. |
| strftime(format, timeTuple) | Inverse of localtime(). Returns a float. |
| mktime(tuple) | Parses a formated string representing time, return tuple as in gmtime(). |
| strptime(string[,format]) | Suspends execution for secs seconds. secs can be a float. |
| sleep(secs) |  |

and also: clock, ctime.

|  |  |
| :---: | :---: |
| Directive | Meaning |
| \%a | Locale's abbreviated weekday name. |
| \%A | Locale's full weekday name. |
| \%b | Locale's abbreviated month name. |
| \%B | Locale's full month name. |
| \% C | Locale's appropriate date and time representation. |
| \%d | Day of the month as a decimal number [01,31]. |
| \% H | Hour (24-hour clock) as a decimal number [00,23]. |
| \% I | Hour (12-hour clock) as a decimal number [01,12]. |
| \%j | Day of the year as a decimal number [001,366]. |
| \%m | Month as a decimal number [01,12]. |
| \%M | Minute as a decimal number [00,59]. |
| \%p | Locale's equivalent of either AM or PM. |
| \%S | Second as a decimal number [00,61]. Yes, 61! |
| \%U | Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0. |
| \%W | Weekday as a decimal number [0(Sunday),6]. |
| \%W | Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0. |
| \% x | Locale's appropriate date representation. |
| \% X | Locale's appropriate time representation. |
| \% Y | Year without century as a decimal number [00,99]. |
| \%Y | Year with century as a decimal number. |
| \% Z | Time zone name (or by no characters if no time zone exists). |
| \%\% | A literal "\%" character. |

## string

Common string operations. [Full doc]
As of Python 2.0, much (though not all) of the functionality provided by the string module have been superseded by builtin string methods - see Operations on strings for details.

| Some string variables |  |
| :--- | :--- |
| Variable | Meaning |
| digits | The string '0123456789'. |
| hexdigits, octdigits | Legal hexadecimal \& octal digits. |
| letters, uppercase, lowercase, whitespace | Strings containing the appropriate characters. |
| ascii_letters, ascii_lowercase, ascii_uppercase | Same, taking the current locale in account. |
| index_error | Exception raised by index () if substring not found. |

| Some string functions | Result |
| :--- | :--- |
| Function | Returns a copy of string $s$ with tabs expanded. |
| expandtabs(s, tabSize) |  |

| find $/ \mathrm{rfind}(s, \operatorname{sub}[$, start $=0[$, end $=0]$ ) | Returns the lowest/highest index in $s$ where the substring sub is found such that sub is wholly contained in s[start:end]. Return -1 if sub not found. |
| :---: | :---: |
| Ijust/rjust/center(s, width[, fillChar=' ']) | Returns a copy of string $s$; left/right justified/centered in a field of given width, padded with spaces or the given character. $s$ is never truncated. |
| lower/upper(s) | Returns a string that is (a copy of) $s$ in lowercase/uppercase. |
| split(s[, sep=whitespace[, maxsplit=0]]) | Returns a list containing the words of the string $s$, using the string sep as a separator. |
| rsplit(s[, sep=whitespace[, maxsplit=0]]) | Same as split above but starts splitting from the end of string, e.g. <br> 'A,B,C'.split(',', 1) == ['A', 'B,C'] but 'A, B, C'.rsplit(',', 1) == ['A,B', 'C'] |
| join(words[, sep = ' ']) | Concatenates a list or tuple of words with intervening separators; inverse of split. |
| replace(s, old, new[, maxsplit=0] | Returns a copy of string $s$ with all occurrences of substring old replaced by new. Limits to maxsplit first substitutions if specified. |
| strip(s[, chars=None]) | Returns a string that is (a copy of) $s$ without leading and trailing chars (default: whitespace). Also: |

## re (sre)

Regular expression operations. [Full doc]
Handles Unicode strings. Implemented in new module sre, re now a mere front-end for compatibility.
Patterns are specified as strings. Tip: Use raw strings (e.g. $r^{\prime} \backslash w^{*}{ }^{\prime}$ ) to litteralize backslashes.

|  | Flags (combinable by \|): <br> I or IGNORECASE or (?i) <br> case insensitive matching <br> L or LOCALE or (?L) <br> make $\backslash \mathrm{w}, \backslash \mathrm{W}, \backslash \mathrm{b}, \backslash \mathrm{B}$ dependent on the current locale <br> M or MULTILINE or (?m) <br> matches every new line and not only start/end of the whole string <br> S or DOTALL or (?s) <br> '.' matches ALL chars, including newline <br> $X$ or VERBOSE or (? x ) <br> Ignores whitespace outside character sets |
| :---: | :---: |
| escape(string) | Returns (a copy of) string with all non-alphanumerics backslashed. |
| match(pattern, string[, flags]) | If 0 or more chars at beginning of string matches the RE pattern string, returns a corresponding MatchObject instance, or None if no match. |
| search(pattern, string[, flags]) | Scans thru string for a location matching pattern, returns a corresponding MatchObject instance, or None if no match. |
| split(pattern, string[, maxsplit=0]) | Splits string by occurrences of pattern. If capturing () are used in pattern, then occurrences of patterns or subpatterns are also returned. |
| findall(pattern, string) | Returns a list of non-overlapping matches in pattern, either a list of groups or a list of tuples if the pattern has more than 1 group. |
| sub(pattern, repl, string[, count=0]) | Returns string obtained by replacing the (count first) leftmost non-overlapping occurrences of pattern (a string or a RE object) in string by repl; repl can be a string or a function called with a single MatchObj arg, which must return the replacement string. |
| subn(pattern, repl, string[, count=0]) | Same as sub (), but returns a tuple (newString, numberOfSubsMade). |

## Regular Expression Objects

RE objects are returned by the compile function.

| re object attributes |  |
| :--- | :--- |
| Attribute | Description |
| flags | Flags arg used when RE obj was compiled, or 0 if none provided. |
| groupindex | Dictionary of \{group name: group number\} in pattern. |
| pattern | Pattern string from which RE obj was compiled. |

| re object methods | Result |
| :--- | :--- |
| Method | If zero or more characters at the beginning of string match this regular expression, returns a <br> corresponding Matchobject instance. Returns None if the string does not match the pattern; <br> note that this is different from a zero-length match. <br> The optional second parameter pos gives an index in the string where the search is to start; <br> it defaults to 0. This is not completely equivalent to slicing the string; the " pattern character <br> matches at the real beginning of the string and at positions just after a newline, but not <br> necessarily at the index where the search is to start. <br> The optional parameter endpos limits how far the string will be searched; it will be as if the <br> string is endpos characters long, so only the characters from pos to endpos will be searched <br> for a match. |
| match(string[, endpos]) |  |
| search(string[, pos][, endpos]) | Scans through string looking for a location where this regular expression produces a match, <br> and returns a corresponding Matchobject instance. Returns None if no position in the string <br> matches the pattern; note that this is different from finding a zero-length match at some <br> point in the string. <br> The optional pos and endpos parameters have the same meaning as for the match () method. |
| split(string[, maxsplit=0]) | Identical to the split () function, using the compiled pattern. |
| findall(string) | Identical to the findall () function, using the compiled pattern. |
| sub(repl, string[, count=0]) | Identical to the sub() function, using the compiled pattern. |
| subn(repl, string[, count=0]) | Identical to the subn() function, using the compiled pattern. |

## Match Objects

Match objects are returned by the match \& search functions.

| Match object attributes |  |
| :--- | :--- |
| Attribute | Description |
| pos | Value of pos passed to search or match functions; index into string at which RE engine started search. |
| endpos | Value of endpos passed to search or match functions; index into string beyond which RE engine won't go. |
| re | RE object whose match or search fct produced this Matchobj instance. |
| string | String passed to match () or search (). |

| Match object functions |  |
| :---: | :---: |
| Function | Result |
| group([g1, g2, ...]) | Returns one or more groups of the match. If one arg, result is a string; if multiple args, result is a tuple with one item per arg. If $g i$ is 0 , returns value is entire matching string; if $1<=g i<=99$, return string matching group \#gi (or None if no such group); gi may also be a group name. |
| groups() | Returns a tuple of all groups of the match; groups not participating to the match have a value of None. Returns a string instead of tuple if len(tuple) $==1$. |
| start(group), end(group) | Returns indices of start \& end of substring matched by group (or None if group exists but didn't contribute to the match). |
| span(group) | Returns the 2-tuple (start(group), end(group)); can be (None, None) if group didn't contibute to the match. |

For intensive number crunching, see also Numerical Python and the Python and Scientific computing page. [Full doc]

| Constants |  |
| :--- | :--- |
| Name | Value |
| pi | 3.1415926535897931 |
| e | 2.7182818284590451 |

| Functions |  |
| :---: | :---: |
| Name | Result |
| $\operatorname{acos}(x)$ | Returns the arc cosine (measured in radians) of $x$. |
| $\operatorname{asin}(x)$ | Returns the arc sine (measured in radians) of $x$. |
| $\operatorname{atan}(x)$ | Returns the arc tangent (measured in radians) of $x$. |
| $\operatorname{atan} 2(x, y)$ | Returns the arc tangent (measured in radians) of $y / x$. Unlike atan ( $y / x$ ), the signs of both $x$ and $y$ are considered. |
| $\operatorname{ceil}(x)$ | Returns the ceiling of $x$ as a float. This is the smallest integral value $>=x$. |
| $\cos (x)$ | Returns the cosine of $x$ (measured in radians). |
| $\cosh (x)$ | Returns the hyperbolic cosine of $x$. |
| degrees( $x$ ) | Converts angle $x$ from radians to degrees. |
| $\exp (x)$ | Returns e raised to the power of $x$. |
| fabs( $x$ ) | Returns the absolute value of the float $x$. |
| floor ( $x$ ) | Returns the floor of $x$ as a float. This is the largest integral value $<=x$. |
| $f m o d(x, y)$ | Returns fmod(x, y), according to platform C. x \% y may differ. |
| $f r \exp (x)$ | Returns the mantissa and exponent of $x$, as pair $(m, e) . m$ is a float and $e$ is an int, such that $x=m * 2 . * * e$. If $x$ is $0, \mathrm{~m}$ and e are both 0 . Else $0.5<=\mathrm{abs}(\mathrm{m})<1.0$. |
| $\operatorname{hypot}(x, y)$ | Returns the Euclidean distance sqrt ( $\left.\mathrm{s}^{*} \mathrm{x}+\mathrm{y}^{*} \mathrm{y}\right)$. |
| Idexp ( $x, i$ ) | x* (2**i) |
| $\log (x[$, base $])$ | Returns the logarithm of $x$ to the given base. If the base is not specified, returns the natural logarithm (base e) of $x$. |
| $\log 10(x)$ | Returns the base 10 logarithm of $x$. |
| $\operatorname{modf}(x)$ | Returns the fractional and integer parts of $x$. Both results carry the sign of $x$. The integer part is returned as a float. |
| pow $(x, y)$ | Returns $x^{* *} y$ ( $x$ to the power of $y$ ). Note that for $y=2$, it is more efficient to use $\mathrm{x}^{*} \mathrm{x}^{\text {a }}$. |
| radians( $x$ ) | Converts angle $x$ from degrees to radians. |
| $\sin (x)$ | Returns the sine (measured in radians) of $x$. |
| $\sinh (x)$ | Returns the hyperbolic sine of $x$. |
| $\operatorname{sqrt}(x)$ | Returns the square root of $x$. |
| $\tan (x)$ | Returns the tangent (measured in radians) of $x$. |
| $\tanh (x)$ | Returns the hyperbolic tangent of $x$. |

## getopt

Parser for command line options. [Full doc]

This was the standard parser until Python 2.3, now superseded by optparse.
[see also: Richard Gruet's simple parser getargs.py (shameless self promotion)]

Functions:

```
getopt(list, optstr) -- Similar to C. <optstr> is option letters to look for.
    put :' after letter if option takes arg. E.g.
    was python test.py-c h1 -a arg1 arg2
    opts, args = getopt.getopt(sys.argv[1:], 'ab:c:')
    # opts would be ('-a' ,')]
    # args would be
    ['arg1', 'arg2']
```

## List of modules and packages in base distribution

Built-ins and content of python Lib directory. The subdirectory Lib/site-packages contains platform-specific packages and modules.
[Python NT distribution, may be slightly different in other distributions]

| Standard library modules |  |
| :---: | :---: |
| Operation | Result |
| aifc | Stuff to parse AIFF-C and AIFF files. |
| anydbm | Generic interface to all dbm clones. (dbhash, gdbm, dbm, dumbdbm). |
| asynchat | A class supporting chat-style (command/response) protocols. |
| asyncore | Basic infrastructure for asynchronous socket service clients and servers. |
| atexit | Register functions to be called at exit of Python interpreter. |
| audiodev | Classes for manipulating audio devices (currently only for Sun and SGI). |
| base64 | Conversions to/from base64 transport encoding as per RFC-1521. |
| BaseHTTPServer | HTTP server base class |
| Bastion | "Bastionification" utility (eontrolaceess to instance vars). |
| bdb | A generic Python debugger base class. |
| bsddb | (Optional) improved BSD database interface [package]. |
|  |  |

| binhex | Macintosh binhex compression/decompression. |
| :---: | :---: |
| bisect | Bisection algorithms. |
| bz2 | BZ2 compression. |
| calendar | Calendar printing functions. |
| cgi | Wraps the WWW Forms Common Gateway Interface (CGI). |
| CGIHTTPServer | CGI-savvy HTTP Server. |
| cmd | A generic class to build line-oriented command interpreters. |
| Emp | Efficiently compare files, boun |
| empere | Same, but eaches'stat' results forspedr |
| code | Utilities needed to emulate Python's interactive interpreter. |
| codecs | Lookup existing Unicode encodings and register new ones. |
| codeop | Utilities to compile possibly incomplete Python source code. |
| collections | high-performance container datatypes. Currently, the only datatype is a double-ended queue. |
| colorsys | Conversion functions between RGB and other color systems. |
| commands | Execute shell commands via os.popen [Unix only]. |
| compileall | Force "compilation" of all .py files in a directory. |
| ConfigParser | Configuration file parser (much like windows .ini files). |
| Cookie | HTTP state (cookies) management. |
| copy | Generic shallow and deep copying operations. |
| copy_reg | Helper to provide extensibility for modules pickle/cPickle. |
| csv | Tools to read comma-separated files (of variations thereof). |
| datetime | Improved date/time types (date, time, datetime, timedelta). |
| dbhash | (g)dbm-compatible interface to bsdhash.hashopen. |
| decimal | Decimal floating point arithmetic. |
| difflib | Tool for comparing sequences, and computing the changes required to convert one into another. |
| dircache | Sorted list of files in a dir, using a cache. |
| diremp | Defines a class to buidedirectory diff toolson. |
| dis | Bytecode disassembler. |
| distutils | Package installation system. |
| distutils.command.register | Registers a module in the Python package index (PyPI). This command plugin adds the register command to distutil scripts. |
| distutils.debug |  |
| distutils.emxccompiler |  |
| distutils.log |  |
| doctest | Unit testing framework based on running examples embedded in docstrings. |
| DocXMLRPCServer | Creation of self-documenting XML-RPC servers, using pydoc to create HTML API doc on the fly. |
| dospath | Common operations on DOS pathnames. |
| dumbdbm | A dumb and slow but simple dbm clone. |
| dump | Print pyon |
| dummy_thread |  |
| dummy_threading | Helpers to make it easier to write code that uses threads where supported, but still runs on Python versions without thread support. The dummy modules simply run the threads sequentially. |
| email | A package for parsing, handling, and generating email messages. New version 3.0 dropped various deprecated APIs and removes support for Python versions earlier than 2.3. |
| encodings | New codecs: idna (IDNA strings), koi8_u (Ukranian), palmos (PalmOS 3.5), punycode (Punycode IDNA codec), string_escape (Python string escape codec: replaces non-printable chars w/ Python-style string escapes). New codecs in 2.4: HP Roman8, ISO_8859-11, ISO_8859-16, PCTP-154, TIS-620; Chinese, Japanese and Korean codecs. |
| exceptions | Class based built-in exception hierarchy. |
| filecmp | File and directory comparison. |
| fileinput | Helper class to quickly write a loop over all standard input files. |
| find | Find files direetory hierarehy matehing a pattern. |
| fnmatch | Filename matching with shell patterns. |
| formatter | Generic output formatting. |
| fpformat | General floating point formatting functions. |
| ftplib | An FTP client class. Based on RFC 959. |
| gc | Perform garbage collection, obtain GC debug stats, and tune GC parameters. |
| getopt | Standard command line processing. See also optparse. |
| getpass | Utilities to get a password and/or the current user name. |
| gettext | Internationalization and localization support. |
| glob | Filename "globbing" utility. |
| gopherlib | Gopher protocol client interface. |
| - | 'trep' utilities. |
| gzip | Read \& write gzipped files. |
| heapq | Heap queue (priority queue) helpers. |
| hmac | HMAC (Keyed-Hashing for Message Authentication). |
| hotshot.stones | Helper to run the pystone benchmark under the Hotshot profiler. |
| htmlentitydefs | HTML character entity references. |
| htmllib | HTML2 parsing utilities |
| HTMLParser | Simple HTML and XHTML parser. |
| httplib | HTTP1 client class. |
| idlelib | (package) Support library for the IDLE development environment. |
| ihooks | Hooks into the "import" mechanism. |
| imaplib | IMAP4 client.Based on RFC 2060. |
| imghdr | Recognizing image files based on their first few bytes. |
| imputil | Provides a way of writing customized import hooks. |
| inspect | Get information about live Python objects. |
| itertools | Tools to work with iterators and lazy sequences. |
| keyword | List of Python keywords. |
| * | A Pythonre implementation of hierarehical module import. |
| linecache | Cache lines from files. |

| Hinuxadiod |  |
| :---: | :---: |
| locale | Support for number formatting using the current locale settings. |
| logging | (package) Tools for structured logging in log4j style. |
| macpath | Pathname (or related) operations for the Macintosh [Mac]. |
| macurl2path | Mac specific module for conversion between pathnames and URLs [Mac]. |
| mailbox | Classes to handle Unix style, MMDF style, and MH style mailboxes. |
| mailcap | Mailcap file handling (RFC 1524). |
| marshal | Internal Python object serialization. |
| markupbase | Shared support for scanning document type declarations in HTML and XHTML. |
| mhlib | MH (mailbox) interface. |
| mimetools | Various tools used by MIME-reading or MIME-writing programs. |
| mimetypes | Guess the MIME type of a file. |
| MimeWriter | Generic MIME writer. Deprecated since release 2.3. Use the email package instead. |
| mimify | Mimification and unmimification of mail messages. |
| mmap | Interface to memory-mapped files - they behave like mutable strings. |
| modulefinder | Tools to find what modules a given Python program uses, without actually running the program. |
| multifile | A readline()-style interface to the parts of a multipart message. |
| mutex | Mutual exclusion -- for use with module sched. See also std module threading, and glock. |
| netrc | Parses and encapsulates the netrc file format. |
| nntplib | An NNTP client class. Based on RFC 977. |
| ntpath | Common operations on Windows pathnames. |
| nturl2path | Convert a NT pathname to a file URL and vice versa. |
| olddifflib | Old version of difflib (helpers for computing deltas between objects)? |
| optparse | Improved command-line option parsing library (see also getopt). |
| OS | OS routines for Mac, DOS, NT, or Posix depending on what system we're on. |
| os2emxpath | os.path support for OS/2 EMX. |
| - | Greate a-self unpacking shell arehive. |
| pdb | A Python debugger. |
| pickle | Pickling (save and restore) of Python objects (a faster C implementation exists in built-in module: cPickle). |
| pickletools | Tools to analyze and disassemble pickles. |
| pipes | Conversion pipeline templates. |
| pkgutil | Tools to extend the module search path for a given package. |
| platform | Get info about the underlying platform. |
| Poly | Polymials. |
| popen2 | Spawn a command with pipes to its stdin, stdout, and optionally stderr. Superseded by module subprocess since 2.4 |
| poplib | A POP3 client class. |
| posixfile | Extended file operations available in POSIX. |
| posixpath | Common operations on POSIX pathnames. |
| pprint | Support to pretty-print lists, tuples, \& dictionaries recursively. |
| pre | Support for regular expressions (RE) - see re. |
| profile | Class for profiling python code. |
| pstats | Class for printing reports on profiled python code. |
| pty | Pseudo terminal utilities. |
| py_compile | Routine to "compile" a .py file to a .pyc file. |
| pyclbr | Parse a Python file and retrieve classes and methods. |
| pydoc | Generate Python documentation in HTML or text for interactive use. |
| pyexpat | Interface to the Expat XML parser. |
| Prunit | Unit test frame |
| Queue | A multi-producer, multi-consumer queue. |
| quopri | Conversions to/from quoted-printable transport encoding as per RFC 1521. |
| rand | Don't use unless you want compatibility with C's rand(). |
| random | Random variable generators. |
| re | Regular Expressions. |
| readline | GNU readline interface [Unix]. |
| reconvert | Convert old ("regex") regular expressions to new syntax ("re"). |
| regex_syntax | Flags for regex.set_syntax(). |
| regexp | Backward compatibility for module "regexp" using "regex". |
| regsub | Regexp-based split and replace using the obsolete regex module. |
| repr | Redo repr () but with limits on most sizes. |
| 比 | Restricteex |
| rfc822 | Parse RFC-8222 mail headers. |
| rlcompleter | Word completion for GNU readline 2.0. |
| robotparser | Parse robot.txt files, useful for web spiders. |
| sched | A generally useful event scheduler class. |
| sets | A Set datatype implementation based on dictionaries (see Sets). |
| sgmllib | A parser for SGML, using the derived class as a static DTD. |
| shelve | Manage shelves of pickled objects. |
| shlex | Lexical analyzer class for simple shell-like syntaxes. |
| shutil | Utility functions for copying files and directory trees. |
| SimpleHTTPServer | Simple HTTP Server. |
| SimpleXMLRPCServer | Simple XML-RPC Server |
| site | Append module search paths for third-party packages to sys.path. |
| smtpd | An RFC 2821 smtp proxy. |
| smtplib | SMTP/ESMTP client class. |
| sndhdr | Several routines that help recognizing sound. |
| socket | Socket operations and some related functions. Now supports timeouts thru function settimeout (t). Also supports SSL on Windows. |
| SocketServer | Generic socket server classes. |

| sre | Support for regular expressions (RE). See re. |
| :---: | :---: |
| stat | Constants/functions for interpreting results of os. |
| statcache | Maintain a cache of stat () information on files. |
| statvfs | Constants for interpreting statvfs struct as returned by os.statvfs() and os.fstatvfs () (if they exist). |
| string | A collection of string operations (see Strings). |
| stringprep | Normalization and manipulation of Unicode strings. |
| StringIO | File-like objects that read/write a string buffer (a faster C implementation exists in built-in module: cStringIO). |
| subprocess | Subprocess management. Replacement for os.system, os.spawn*, os.popen*, popen2.* [PEP324] |
| sunau | Stuff to parse Sun and NeXT audio files. |
| sunaudio | Interpret sun audio headers. |
| symbol | Non-terminal symbols of Python grammar (from "graminit.h"). |
| symtable | Interface to the compiler's internal symbol tables. |
| tabnanny | Check Python source for ambiguous indentation. |
| tarfile | Tools to read and create TAR archives. |
| telnetlib | TELNET client class. Based on RFC 854. |
| tempfile | Temporary files and filenames. |
| textwrap | Tools to wrap paragraphs of text. |
| threading | Proposed new threading module, emulating a subset of Java's threading model. |
| threading_api | (doc of the threading module). |
| timeit | Benchmark tool. |
| toaiff | Convert "arbitrary" sound files to AIFF (Apple and SGI's audio format). |
| token | Token constants (from "token.h"). |
| tokenize | Tokenizer for Python source. |
| traceback | Extract, format and print information about Python stack traces. |
| trace | Tools to trace execution of a function or program. |
| tty | Terminal utilities [Unix]. |
| turtle | LogoMation-like turtle graphics. |
| types | Define names for all type symbols in the std interpreter. |
| tzparse | Parse a timezone specification. |
| unicodedata | Interface to unicode properties. |
| unittest | Python unit testing framework, based on Erich Gamma's and Kent Beck's JUnit. |
| urllib | Open an arbitrary URL. |
| urllib2 | An extensible library for opening URLs using a variety of protocols. |
| urlparse | Parse (absolute and relative) URLs. |
| user | Hook to allow user-specified customization code to run. |
| Heer | A wrapper to allow subclassing of built-in dict class (useless with new-style classes. Since Python 2.2, dict is subclassable). |
| Hsertist | A wrapper to allow subclassing of built-in list class (useless with new-style classes. Since Python 2.2, list is subclassable) |
| HserString | A wrapper to allow subclassing of built-in string class (useless with new-style classes. Since Python 2.2, str is subclassable). |
| + | some usefulfunctions that don't fitelsewnere |
| uu | Implementation of the UUencode and UUdecode functions. |
| warnings | Python part of the warnings subsystem. Issue warnings, and filter unwanted warnings. |
| wave | Stuff to parse WAVE files. |
| weakref | Weak reference support for Python. Also allows the creation of proxy objects. |
| webbrowser | Platform independent URL launcher. |
| whatsound | Sevelratines that help reognizing sound files. |
| whichdb | Guess which db package to use to open a db file. |
| whrandom | Wichmann-Hill random number generator (obsolete, use random instead). |
| xdrlib | Implements (a subset of) Sun XDR (eXternal Data Representation). |
| xmllib | A parser for XML, using the derived class as static DTD. |
| xml.dom | Classes for processing XML using the DOM (Document Object Model). 2.3: New modules expatbuilder, minicompat, NodeFilter, xmlbuilder. |
| xml.sax | Classes for processing XML using the SAX API. |
| xmlrpclib | An XML-RPC client interface for Python. |
| xreadlines | Provides a sequence-like object for reading a file line-by-line without reading the entire file into memory. Deprecated since release 2.3. Use for line in file instead. Removed since 2.4 |
| zipfile | Read \& write PK zipped files. |
| zipimport | ZIP archive importer. |
| zod | Demmatration of abstruse mathematieal coneeptor. |

## Workspace exploration and idiom hints

```
dir(<module>)
if name == ' main '. main()
if name__== '_main__': main()
map(None, Ist1, \overline{lst2, -..)}
b}=\textrm{a}[:
list functions, variables in <module>
get object keys, defaults to local name space
invoke main if running as script
nvoke main if running as script
merge lists
reate copy of seq structure
(underscore) in interactive mode, is last value printed
```

## Python Mode for Emacs

Emacs goodies available here.
(The following has not been revised, probably not up to date - any contribution welcome -)

```
Type C-c ? when in python-mode for extensive help.
INDENTATION
Primarily for entering new code:
    TAB indent line appropriately
    LFD insert newline, then indent
DEL reduce indentation, or delete single character
frimarily for reindenting existing code:
    c-c : guess py-indent-offset from file content; change locally
    c-u C-c : ditto, but change globally
    C-C TAB reindent region to match its context
    -c < shift region left by py-indent-offset
MARKING & MANIPULATING REGIONS OF CODE
C-c C-b mark block of lines
M-C-h mark smallest enclosing def
C-u M-C-h mark smallest enclosing class
C-c # comment out region of code
C-u C-c #
C-c C-p move to statement preceding point
C-c C-n move to statement following point
C-c C-u move up to start of current block
M-C-a move to start of def
C-u M-C-a move to start of class
M-C-e move to end of def
C-u M-C-e move to end of class
EXECUTING PYTHON CODE
C-C C-c sends the entire buffer to the Python interpreter
C-c sends the current region
C-c ! starts a Python interpreter window; this will be used by
    subsequent C-c C-c or C-C | commands
VARIABLES
py-indent-offset indentation increment
py-block-comment-prefix comment string used by py-comment-region
py-python-command shell command to invoke Python interpreter
py-scroll-process-buffer t means always scroll Python process buffer
py-temp-directory directory used for temp files (if needed)
py-beep-if-tab-change ring the bell if tab-width is changed
```
